Many fire-balls and shooting-stars leave a luminous train behiud them, similar to a bright band of phosphorescent light. These trains, for the most part, disappear in a few seconds; but sometimes they continue for several minutes. In the case of actual fire-balls, Olbers observed trains whicb continued for six or seven minutes; Brandes, in one instance, 15 minutes; Prof. Newton, of New Haven, saw one in which the duration of train was 45 minutes; and cases have heen reported in whicb more than an *hour* elapsed between the extinction of the fire-hall and the disappearance of the luminous train. This bright narrow bar of light is frequently several degrees long; it usually retains its elongated form for a fraction of a minute, and then becomes *curved*. If it lasts several minutes, the train gets *twisted* forms, the result, doubtless, of winds in the upper air and of currents produced by the transit of the meteor itself.

Chemical Constitution.

On examining and comparing the chemical constitution of these meteoric masses, which reach the surface of the earth, the first circumstance that strikes us as remarkable, is their perfect resemhlance to each other in their *chemical composition*. Chemical analysis gives, in almost every instance, the same substances, combined in very nearly the same proportions. This seems to be the case with both of the two great classes of meteoric stones, viz: the *stony* and *metallic* ærolites. These common and constant characters indicate a *common origin*.

The New Yellow Jacket Shaft.

Work has recently been commenced, says the Virginia *Enterprise*, in the Yellow Jacket new shaft from the drift on the 2200 level to meet the workmen who are coming down. The rock at the bottom where the work of raising has been commenced is found to be exceedingly hard. In drilling a single inch the point of a drill is blunted as though it had heen battered upon a block of steel. This rock is a species of black porphyry, much resembling basalt in appearance. It is merely a narrow belt or rih. Air for the use of the miners is supplied through a large pipe from the 2000 level of the old works, and is furnished hy a blower tbat is run in the mine hy water power. The air is carried a distance of 1,400 feet.

It is hoped that the new shaft will prove a downcast and it is thought that it will so turn out, as the air in the new shaft is quite cold, while at the old works it is very hot; also, in the Imperial and otber mines with which there are connections. As this hot air rushes to the surface through the various old shafts with great force, it will undoubtedly draw the cold air from the new shaft to the westward. This will be a good thing for the new shaft and not a had thing for the old mines, as it will bring into their lower levels a great volume of pure cold air.

A strange thing about the Yellow Jacket new shaft is its coldness at the bottom, notwithstanding its depth and the great heat of the rock through which it is passing. The men are obliged to work with their coats on, owing to the cold, while the rock in which they are at work is intensely hot, as also is the little water that is found.

At the depth of 2,165 feet a standard thermomcter was placed in a drill hole 33 inches in depth, when a temperature of 133° was shown. This is much hotter than any rock found in the Sutro tunnel. The highest rock temperature in the Sutro tuunel has been 110°.

It is found that some belts or strata of rock are hotter than others. The temperature of the rock at the depth at present attained has not been tested, therefore it may he cooler thau above. In the end of the 2200 drift, at the shaft, it is very hot, however. In extending the air pipe a day or two since the men carried in two joints coupled together and it was all that the best seasoned among them could do to remain long enough to put them in place.

Until recently it was thought that there yet remained 50 feet of drift to he run to get under the shaft, but a survey made showed it to be under the shaft. It appears that the hlock of 50 feet was taken out hy Supt. Taylor previous to his resignation.

The Engineer.

Railway Building for the Coming Year.

A correspondent of the *Railway Age*, who has been largely engaged in railway building, takes a very enthusiastic view of the prosperity of that business in the immediate future. He anticipates a vast influx of population into the Western States and Territories, during the next few years, by reason of the present business depression and unsettled political condition of Europe, which will both add largely to the receipts and furnish cheap material and labor for construction purposes. Speaking of the coming immigration, he says:

During the past five years, commencing with March of this year, there will be a tide of immigration setting in from the East, and by the East I mean not only our own Puritan New England, but from the healthiest, strongest and best element of the Eastern countries—Prussia, Norway, Sweden, Schleswig-Holstein, etc., an agricultural people, seeking homes of their own. One million of them are on the Western prairies now. They write home (we will say) 10,000 letters a year. These 10,000 letters, couched in different languages, are repeated 10,000 times, and finally reach the ears of twice as many more. Hence, these people will come to the country where they can make a home competence for their wives and families.

Now, this being so, it is self-evident that means of access must be furnished to the cheap lands of Dakota, Minnesota, Arizona, Kansas and southwestern Kansas, as well as Missouri, the Indian Territory, and the West, even to the Pacific ocean.

On the question as to the development of the country and construction of railways, he says: Immigrants in coming to new countries always seek the same latitudes. The Swede and Norwegian want Minnesota, as well as do many of our hardy people from the Eastern States. The German wants central Wisconsin, but goes most everywhere, as does the American. The Englishman is conservative, and "waits." All these people will seek as they come, rapid transit, and railways are the most rapid. For this reason, the vast multitude that are coming westward year by year will be increased this year, and the next and the next, until there will be smiling homes and cottages and school houses and churches, in all the west, southwest and northwestern country, even to Alaska, which Mr. Seward was laughed at for purchasing for a less sum than a New York capitalist can get into good society on. Hardly a lady to-day but is petting the Alaska seal sacque she wears.

Leadville, Colorado, and the mines in Montana, and the general development of mining interest, with the accompanying influx of population, demands roads. Also quick communications of wealth taken from the earth, both in mining and agriculture, give means to build roads. Capital is going into the development of these mines, and they are yielding immense profits since improved machinery has been put into them.

Agricultural, mineral and animal products alone will increase the mileage of construction for years to come. This year it will be increased 2,000 miles over 1878. This will include many narrow-gauge roads as well as standards.

Irrigation in Tulare.—Assistant State Engineer, A. C. Warfield, Jr., informs the Fresno *Expositor* that his labors, during the past season, have been devoted to running grade lines and making a complete topographical survey of the county along the foothills from King's river to the Kaweah, and from the Kaweah to Tule river, and thence to White river. Also a survey and examination of King's river from the foothills to the railroad, including an examination of the various canals diverging therefrom, and measurement of their capacity, velocity, etc. For greater accuracy, on all the principal rivers, from the Merced to Tule river, surveys have been made at two points, one near the foothills and the other near the railroad; and gauges have been established at these points in order to determine the amount of water flowing in the various streams at different seasons of the year. Rain gauges have also been established at various points, and the rainfall will be from time to time compared with the rise of the water in the river, so as to determine the influence on the various streams. The information thus obtained is so costly that individual enterprise could not afford to seek after it, and hence the necessity of the State taking hold of it. It will be of great value in determining accurately the water supply of this valley.

"On to the Rio Grande."—Mr. Wm. Hood, chief engineer of the Southern Pacific, says the *Arizona Citizen* of Jan. 18th, arrived in town with his wife on Saturday last and took up their quarters at the Palace. On Monday Mr. Hood and a small party left for El Paso, Texas, and will make a preliminary survey for the purpose of determining upon the most practicable route for the railroad from Arizona through New Mexico to the Rio Grande.

The Metropolitan Elevated.—The Metropolitan Elevated Railway Company, of New York, on Jan 21st, awarded the contract for the construction of its East Side line from the Battery to Harlem.

Useful Information.

A Method for Mending Broken Castings.—Mr. C. de Laharpe gives a method for mending broken castings, which may, in many cases, prove valuable in an emergency. It consists of heating the two pieces together by a stream of molten cast-iron until the parts near the line of breakage commence to melt. At exactly that point the flow of cast-iron is stopped, and a small quantity of metal is left behind, which, in chilling, unites the two parts. If the operation is well conducted, the piece thus mended will break more readily at any other part than the new seam. It is necessary, in order to be successful, to induce melting of the broken edges over their whole length, and therefore the thickness of the casting must not be too small in comparison to its length, nor should there be, in the direct vicinity of the fracture, any marked irregularities of thickness. The broken part must also be perfectly independent of the rest, or else the expansion and contraction will cause breaking. The Chinese have noticed this method of mending broken cast-iron vessels from time immemorial.

Self Luminous Clock Dials.—The clocks with illuminated dials which made such an impression at the Paris exposition, were perfectly luminous in the dark if exposed to the light during the day. President Morton, of the Stevens Institute of Technology, has recently analyzed the substance with which the dials were coated, and found it to consist of nothing but sulphide of calcium, attached by means of some resinous medium like varnish. This substance is a phosphorescent quality never before equaled. One of the dials was still visible in total darkness after having been shut up in a box for five days. Prof. Morton suggests that if further advances should be made in this direction, it is easy to imagine some wonderful results, before which Mr. Edison's new electric burner would fade into insignificance. Thus if our walls were painted with such a substance they would absorb light enough during the day to continue luminous at night, and thus render all sources of artificial light useless. The coloring of houses on the outside with a like material would also obviate need of all street lamps.

Depreciation of Coal by Storage.—A case having come before the Bohemian courts, it was found that bituminous coal stored 12 months depreciated as follows: 1. English Peases West coal suffered no depreciation. 2. Ibbenbueren, Westphalian coal lost 1.4% in weight, 6% in calorific value and made 4.6% less of coke. 3. Dortmund coal lost 2.6% in calorific value and made 2.1% less of coke. 5. Gelsen Kirchen coal 0.4% loss of weight, 0.6% loss of calorific value and 2.1% loss of yield of coke. 5. Borgloh coal respectively 2.6% and 1.5%. Experts have testified that a loss of 2%, in transportation by cars, was not extraordinary for bituminous coals.

Lining for Boilers.—Mr. Frantz Beuttgenhach gives the following recipe for the preparation of a coating for the inside surface of boilers to prevent the formation of scale: Gradually dissolve 5 lbs. of a mixture of 25 parts of colophonium, 2½ parts of graphite, and 2½ parts lamp black in 40 lbs. of boiling gas tar, adding about 1 lb. tallow. The solution is diluted with about 50% of petroleum and applied in a warm state. It has a pungent smell and should be put on rapidly, the precaution of using closed lanterns being necessary. Its effect is to cause the scale to come off in large flakes when picked.

Solidifying Petroleum.—The *Engineer* says: "It may be useful to note that the lightest petroleums may be partially solidified by mixing them with an aqueous decoction of soapwort. A mucilage forms which is so thick that the containing vessel can be overturned without any portion running out. In this form might it not be useful for some lubricating purposes? If a few drops of phenic acid are stirred into the mucilage, it soon becomes liquid again."

Brass Solder for Iron.—Melt the plates of brass between the pieces that are to be joined. When the work is very fine the parts to be brazed should be covered with powdered borax, melted with water so that it may mix with the brass powder which is to be added to it. Expose the piece to a clear fire in such a manner that it shall not touch the coals and let it remain till the brass begins to run.

Cast-Steel.—If a piece of cast-steel be made red-hot and is quenched in cold water it will become longer, but if the same operation be performed upon a piece of wrought-iron it will become shorter. The precise amount of the alteration, or its variation in different qualities of each metal, has never been determined, although it is of great importance in workshop manipulation.

Lead Explosions.—Many mechanics have had their patience sorely tried when pouring lead around a damp or wet joint, to find it explode, blow out, or scatter, from the effects of steam generated by the heat of the lead. The whole trouble may be stopped by putting a piece of resin the size of the end of a man's thumb, into the ladle and allowing it to melt before pouring.

Fermentation of Grape Juice.—This fermentation is exclusively due (according to M. Pasteur) to the presence of cells of yeast on the surface of the grapes whither the air has brought them. If these cells be suppressed, fermentation should be thereby rendered impossible. Now, in the Jura, it is found that the grapes do not bear any traces of these cells until the end of July. Hence if they are then protected from the dust of the air, it should be possible to bring them to ripeness without the juice being afterwards able to ferment. On this supposition M. Pastear placed grapes in inclosures where all access of atmospheric dust was rigorously prevented. More simply, he enveloped grapes in wadding, raised previously to a temperature of 100° C. He showed in the French Academy grapes ripened under these conditions, and he affirmed that one might crush them and keep them any length of time at the suitable temperature without the least fermentation taking place.

Black Finish for Brass.—Optical and philosophical instruments made in France often have all their brass surfaces of a fine dead black color, very permanent and difficult to imitate. The following, obtained from a foreign source, is the process used by the French artisans: Make a strong solution of nitrate of silver in one dish and of nitrate of copper in another. Mix the two together and plunge the brass into it. Remove and beat the brass evenly until the required degree of dead blackness is obtained.

We produce 50 bushels of grain per head, estimating our population at 40,000,000, while Europe, with a population of not quite 300,000,000, produces only 16 bushels per head, and Great Britain only four bushels per head. It being estimated that the average consumption of grain per head is 15 bushels, we produce three times as much as we require, Russia not twice its wants, and Great Britain not much over one-fourth her requirement.

Good Health.

A Dangerous though Popular Eye-Water.

It is a popular impression that a dilute solution of "sugar of lead," or acetate of lead, is a perfectly harmless application for any slight inflammation of the eyes. The time was when it was so regarded by physicians, who were in the habit of ordering a little acetate of lead dissolved in rose water, with perhaps a few drops of laudanum added, for these ocular ailments. But the use of the lead salt for this purpose was long ago condemned by the best authorities, and most physicians are now aware of the fact. In domestic medicine, however, new ideas are slow in replacing the old ones that have come down from the grandmothers, and sugar of lead is still a favorite basis for home-made eye-waters.

A recent article in the Philadelphia *Medical and Surgical Reporter*, by Dr. W. S. Ross, gives a succinct statement of the reasons why this use of lead salts is dangerous. The Doctor says that the great danger of the use of lead in the eye is that a deposit often takes place on the cornea, especially if the cornea is in the least abraded, from whatever cause. Ulceration of the cornea is a very common occurrence, especially where there is high inflammation in the conjunctiva and sclerotic. If the acetate of lead is used, in solution, in an ulcerated condition, it does not matter of what strength, there will be a deposit of albuminate of lead the entire extent of the cornea denuded.

The opinions of quite a number of distinguished medical writers are quoted to the same effect. One writer says: "This bad effect may result from a single application. The deposit is extremely apt to fix itself on ulcers of the cornea. It attacks every abrasion on the slightest denuded surface. Hence, when such exist, acetate of lead should never be used."

This deposit resembles wet chalk, and can be removed only with difficulty and at considerable danger to the sight of the eyes, especially if the patient is advanced in years.

Bee Stings for Rheumatism.—The *Praeger Wochenblatt* contains the following in regard to the cure of rheumatism by the means of bee stings. The correspondent says that his wife having suffered so much as to be unable to enjoy any rest or sleep for the space of six months, the right arm being almost lame, preventing the sufferer from doing any household work, making her even unable to dress or undress herself, and having heard that a farmer, quite incapacitated by rheumatism, had been accidently stung by bees, and thereby got entirely cured, he persuaded his wife to try this remedy, as the pain from the sting of the bees would not be greater than that already suffered. Three bees were therefore laid and pressed upon the right arm for a considerable time, in order that the poison bladder of the insects should entirely empty itself. The effect produced was astonishing, as the lady, even on the first night, was enabled to enjoy a long, good sleep, the first time for at least six months, the racking pain being entirely gone. The arm was, of course, swollen greatly in consequence of the sting, but the swelling gradually disappeared upon the application of some cooling lotion. All pain was gone, the lame arm recovered its previous vigor, and not the least sign of rheumatism has since showed itself.

The Necessity of Plenty of Sleep.

A writer in *Scribner*, considering "The Relations of Insanity to Modern Civilization," speaks of the loss of sleep as a prominent cause of insanity. He says: "During every moment of consciousness the brain is in activity. The peculiar process of cerebration, whatever that may consist of, is taking place; thought after thought comes forth, nor can we help it. It is only when the peculiar connection or chain of connection of one brain-cell with another is broken and consciousness fades away into the dreamless land of perfect sleep, that the brain is at rest. In this state it recuperates its exhausted energy and power, and stores them up for future need. The period of wakefulness is one of constant wear. Every thought is generated at the expense of brain-cells, which can be fully replaced only by periods of properly regulated repose. If, therefore, these are not secured by sleep; if the brain, through overstimulation, is not left to recuperate, its energy becomes exhausted, debility, disease, and, finally, disintegration supervene. Hence, the story is almost always the same; for weeks and months before the indications of active insanity appear, the patient has been anxious, worried and wakeful, not sleeping more than four or five hours out of the 24. The poor brain, unable to do its constant work, begins to waver, to show signs of weakness or aberration; hallucinations or delusions hover around like floating shadows in the air, until finally disease comes, and—

> "'plants his siege
> Against the mind, the which he pricks and wounds
> With many legions of strange fantasies,
> Which in their throng and press to that last bounds
> Confound themselves.'"

Cooked Celery for Rheumatism.

The many who are fond of the crisp leaf stems of celery would hesitate before reducing it to the estate of "cooked stuff," and yet it is said to be of good taste and to have "virtues" besides. An English writer proclaims cooked celery as a cure for rheumatism, which it certainly will not harm if it fails to cure. We read as follows: Celery, cooked, is a very fine dish, both as nutriment and as a purifier of the blood. I will not enumerate the marvelous cures I have made with celery, for fear the medical men should, like the corn dealers, attempt to worry me. Let me fearlessly say that rheumatism is impossible on such diet. Plainly let me say, cold or damp never produces rheumatism, but simply develops it. The acid blood is the primary cause and the sustaining power of evil. While the blood is alkaline there can be no rheumatism and equally no gout. I must return to cooked celery. Cut the celery into inch dice; boil in water until soft. No water must be poured away unless drunk by an invalid. Then take new milk, slightly thicken with flour and flavor with nutmegs; warm with the celery in the saucepan; serve up with diamonds of toasted bread round dish, and eat with potatoes."

Sanitary Uses of Gunpowder.—A correspondent writes us from the Sandwich Islands saying that during a long life spent in tropical fever districts he has been able to escape infection and miasma by the use of gunpowder, supplemented by a few simple precautions against sudden changes of temperature, sunstroke, bad water and the like. He uses no water that has not been boiled and afterwards kept from air contact; but his main reliance is upon the practice of burning a thimbleful of gunpowder in his bedroom and very small quantities in his trunk, wardrobe, etc., so as to keep his clothes in an atmosphere feebly charged with gunpowder gas. In Madagascar, Reunion, Mauritius, the east coast of tropic Africa, and other fever-smitten lands he has found such simple means a sure preventive of epidemic and epidemic diseases, and has thereby been often brought to the philosophic reflection that gunpowder is destined to invert the aim intended by its fabrication.—*Scientific American.*

Singular Case of Poisoning.—The *Sutter Banner* says that three children of James C. Gray, residing near Yuba City, came near poisoning themselves during the week by chewing the inside bark of the common black locust tree, several of which their father was trimming. The children, aged respectively three, six and nine years, had picked up the twigs, and stripping the inside bark from them, chewed it, swallowing some of the juice. Soon after they were attacked with vomiting, and after thus relieving their stomachs, sat around in a kind of dazed condition, conscious, but with an evident wish to be undisturbed. Dr. Hamlin was called in, and under his ministrations they have about recovered. The fact that poison exists in this tree will doubtless be news to many of our readers, and we publish this that others may exercise care in its handling.

To Cleanse the Hair.—Ammonia should not be used on the hair; it injures the gloss and softness, causing the hair to become harsh and dry. The best way to cleanse the hair, and keep the scalp healthy, is to beat up a fresh egg, and rub it well into the hair, or, if more convenient, rub it into the hair without beating. Rub the egg in until a lather is formed; wet the bands in warm water, softened with borax; by the time a lather is formed, the scalp is clean; then rinse the egg all out in a basin of warm water containing a tablespoonful of powdered borax, after that rinse in one of clear warm water.

The Week.

From the north, south, and center of the State cheering statements come to us of abundant rainfall and encouraging prospects for crops. The length and steadiness of the storm has entirely quieted the uneasy feeling of despondency which had crept over the agricultural districts, and not only the grain grower and fruit producer, but the stock raiser and the wool grower partake of the general feeling of encouragement and prophecy better times. After the months of doubt and anxious expectancy as to the action of Congress on the Chinese question, this week has brought no satisfaction in the passage of the Anti-Chinese bill through the Senate and its return to the House. There is little doubt but that it will become a law. Among mining men some excitement and indignation is manifest over the action of the Bonanza companies in turning hot water into the Sutro tunnel. The Bodie strike is over. The miners have failed in their undertaking and the loss is mostly on themselves. From the East the welcome news comes that the definite treaty between Russia and Turkey has taken effect, and that the Russian troops have been ordered home. The citizens of Alaska have appealed for aid against the incursions of the Indians; and it is humiliating that their request should have to be made to the British corvette *Osprey*, no American force being near enough to protect them. It is just to our Government, however, to state that it has already troops under way to the scene of difficulties to look after its interests. The collision of the local ferry boats in the fog looks strongly as if there was extreme carelessness somewhere, and it is almost a miracle that no lives were lost.

The Snake River Mines.

We have lately received letters from parties in different sections of the country asking for information in regard to the Snake River mines; some of these parties inquiring also about the agricultural lands in that region, the general features of the country, cost and best routes for getting there, climate, seasons, etc. We have within the past few months published a number of editorial articles, communications, extracts from other papers, etc., upon this subject. Still, as these mines are beginning to attract a good deal of attention, having been widely noticed, of late, in the Idaho and Utah press, we will endeavor to give such additional information as may best meet the inquiries above alluded to.

Snake river, which takes its rise in the Wind River range, the highest portion of the Rocky mountains, runs first west for 300 or 400 miles and then turning north, flows about an equal distance, where it unites with the Columbia. From the last of May till the 1st of August, when the snow is melting in the mountains, it carries as much water as the Sacramento at ordinary stages, but much less during the rest of the year, being lowest from the last of September till the 1st of May. Its principal confluents are a North and a South Fork, which unite after they have left the higher mountains. The main stream runs first for about 200 miles through a canyon with sloping banks, deep but not difficult to approach. It then enters and, for the next 100 miles, flows through a gorge having nearly perpendicular walls, rendering approach at many places impossible, and everywhere difficult. There is at the Fort Hall Indian reservation a considerable extent of good land, with some patches elsewhere along the river; the total amount of land fit for cultivation being however very small. The Snake is a timberless stream, as much so as any other river on the continent for its length. There are forests of the kind usually found in the Wasatch and Rocky mountain ranges along its upper portions, but below this it is almost wholly without useful timber of any kind whatever. There are, in places, a sparse growth of cottonwood, some willow, and at a few points small, scattered groves of spruce and pine, one of these being found just below the great Shoshone falls, the spray from which has caused their growth, there being from this point not another tree of any kind in sight. Further down the stream some coniferous trees are also met with. For the most part, however, the inhabitants along and near the Snake have to depend upon sage brush for their fuel.

Besides being so nearly timberless, the country through which this river flows is exceedingly dry and barren. Not only are the fertile bottom lands along it of limited extent, but the entire plateau for a hundred miles or more on either side is an absolute desert, with only here and there a productive strip of land bordering the streams that at long intervals make into the main river. The country produces a great deal of bunch grass, but has so little water that it is almost useless for grazing purposes. There are some fine stock ranges on Raft river and other of the lower confluents of the Snake, but these have all been occupied for many years, leaving but little chance for new comers to that region, whether their object be cattle raising or farming. In regard to the climate, the summers here are warm and the winters cold, much as everywhere else in the Great Basin, the general level of the country having an altitude of about 5,000 feet.

The first discovery of gold on Snake river was made in the fall of 1869, when the few adventurers who had happened to drift into that region proceeded to lay claim to every thing in sight. Not much work was done that year, but the news of discovery spreading abroad, a considerable emigration set that way early the following spring, the number of miners on the river numbering nearly 1,000 by the first of June of that year. By the time the most of them got in, the water was too high to admit of their doing much, and, as everything was claimed and held at high prices, the majority of them left; being discouraged at the prospect of having to wait so long for the river to fall; few of them, moreover, having the means or being disposed to buy claims at the exorbitant prices set upon them. Where any were sold they brought from $50 to $500 each, some credit being, in most cases, given.

Before the high stage of water the miners here had made from six to ten dollars per day working with rockers, which was about the rate averaged throughout the year. In September some began washing with sluices, at which rather more was made. The section of the river along which these diggings were found, commenced near Salmon Falls and extended 50 or 60 miles up.

By the spring of 1871, the cream had been so far skimmed from the richer bars that the claim holders, generally a thriftless set, began to feel like disposing of their interests in them. But the white population having mostly left it was not now so easy to find purchasers. In this emergency these properties were offered to the Chinese, who had up till that time been excluded from the diggings. With the exception of a few rich claims, everything along the river fell that year into the hands of these people, who proceeded to work out the bars here in their quiet and patient way, making what to them were satisfactory wages.

Having lost all interest to the public, nothing more was heard of these Snake River placers from this time on till the past summer, when public attention began to be turned once more towards this long neglected and nearly forgotten region. Now, great difficulty had from the first been experienced in saving the gold found on these Snake River bars, because of its exceeding fineness, scarcely any of the particles being larger than the grains of ordinary black sand, from which size they diminish to microscopic fineness. Washing with the gold-saving appliances before in use, a large percentage of the gold actually contained in the gravel here was lost, a result that had much to do with causing the early abandonment of these diggings by the whites.

Last year parties experimenting with this material introduced silver-coated copper plates into their sluices, which proved so effectual in saving the fine gold, that they were able to make good wages where scarcely anything could be made washing in the old way. This fact becoming known, soon induced others to have recourse to the same method, and being found to work so well, had the effect to awaken a general interest in these mines. In the meantime new placers had been discovered higher up the river, as well as additional deposits on the bars and along its banks further down, whereby the field of practical operations has undergone great enlargement. It is even said that the diggings at some point along the stream are not confined to its channel or immediate banks, but extend back some distance into the plains adjacent. The dust is, however, everywhere extremely fine, being what is known as float or flour gold, and capable, therefore, of being saved only by the appliance above mentioned.

Now, while these placers would appear to be tolerably extensive and capable of yielding fair wages to parties who may succeed in securing good ground and have the means for outfitting and introducing water upon it, it should be borne in mind by those who may think of emigrating to that region, that it requires a considerable amount of money to effect the above objects. There is no water to be had here for washing, except that taken from Snake river. The bars and ground to be operated upon lie at a considerable elevation above the stream, necessitating the construction of ditches often several miles long, a work that in this country can be accomplished only at a considerable expense. In other words, this preliminary outlay will vary from one to three or four thousand dollars, according to the length of the ditches to be built and the magnitude on which operations are to be carried on. Men who go there without that amount of money at command, will stand but a poor chance of being able to work ground on their own account, and will almost, necessarily, have to work on hire for others. As there will be no great demand for labor in diggings of this kind, wages will not be high, while the cost of living will be considerable. In 1870, the wages paid hired men on Snake river, varied from $3 to $4 per day, they finding themselves. These will probably be about the rates that will obtain in these diggings the coming summer.

Travel to and from that country will be found a costly item. From the west it is reached over the Central Pacific railroad, the point where the traveler leaves the railroad, depending upon what portion of the diggings he wishes to go to. If destined for any point much below the crossing of the Kelton and Boisee road, he will leave at Humboldt Wells, whence there is a fair wagon road and a good pack trail to the river. As there is, however, no public conveyance across this route, parties taking it will have to procure riding and pack animals at the Wells, where they can generally be obtained at moderate prices. Parties destined for any point on the river not far below, or within sixty or eighty miles above this crossing, will leave the railroad at Kelton, whence there is a good wagon road and daily stage to the river. From this place there is also a good wagon road to Fort Hall, situated on the river, over one hundred miles above the Boisee crossing, this being the old emigrant trail. At Kelton it is not easy to get either riding or pack animals for prosecuting this part of the journey. Those desirous of going to any point on the river above Fort Hall—and this we take it will be the case with the majority—will go on to Corrinne, and there leaving the Central Pacific, take the Utah Northern railroad, now completed to Snake river.

The distance from the Central Pacific road to the Snake varies from one hundred and twenty to one hundred and fifty miles, according to the point to be reached. This part of the journey, unless made over the Utah Northern narrow-gauge road, cannot be accomplished with much expedition or comfort, as it lies over a dry and sterile country, tolerably level and well supplied with bunch grass, but badly off for both wood and water. The man who leaves California or Nevada for the Snake River country, depending upon getting employment there, should have, at least, a couple of hundred dollars to start with, the one to take him out, and the other to bring him back, in case he wants to come. Without observing this precaution, there is danger that the scenes of 1870 will find repetition this summer. From June to October of that year, scores of men were to be seen making their way back from Snake river on foot, the most of them sleeping in haystacks, and begging their meals along the road. Adventurers who go out there with the purpose of getting hold of a mining claim, and putting the same in shape for successful working must, as before stated, have a considerable amount of means, or they will very likely come short of their aim, if they are not wholly disappointed.

While the published accounts from that region are mostly encouraging, some of them extremely flattering, it should be remembered how generally such has been the case in regard to this class of discoveries; there being almost always, between claim holders, merchants, stage men and other common carriers, so many interested in exaggerating their importance, and thereby exciting a premature and unhealthful emigration. Then, too, by this time, the best and most available ground is already taken up, and if for sale, held at high prices; leaving those who go in now little chance to get hold of anything valuable by location. For nearly a year past, that country has been full of claim hunters, who, if they have not managed to secure everything worth taking up, have proved false to the traditions of their class, more especially of the average Snake River prospector.

Chinese Immigration.

The leading event in men's minds during the week has been the passage by the Senate of the House bill restricting Chinese immigration. This measure seems to represent the views of a great majority of the people as expressed by the Constitutional Convention and the public prints. The bill now goes back to the House for concurrence in the Senate amendments and then to the President for his signature or veto, as the event shall prove.

The following is the full text of the bill as it passed the Senate.

Be it enacted, etc., That no master of any vessel owned in whole or in part by a citizen of the United States, or by a citizen of any foreign country, shall take on board each vessel at any port or place within the Chinese Empire, or at any other foreign port or place whatever, any number exceeding 15 Chinese passengers, whether male or female, with the intent to bring such passengers to the United States, and leave such port or place and bring such passengers to any number exceeding 15 on one voyage within the jurisdiction to the United States.

Sec. 2. That whenever the master or other person in charge of any vessel takes on board the same at any foreign port or place any greater number of Chinese passengers than is prescribed in the first section of this act, with intent to bring such passengers to the United States, and leave such port or place, and bring such passengers to any number exceeding 15 on one voyage, within the jurisdiction of the United States, he shall be deemed guilty of a misdemeanor, and shall, for each passenger so taken on board and brought within the jurisdiction of the United States, exceeding the number of 15, be fined $100, and may also be imprisoned for not exceeding six months.

Sec. 3. That the master of any vessel arriving in the United States, or of any of the Territories thereof, from any foreign place whatever, at the same time that he delivers a manifest of the cargo, and if thereby no cargo, then at the time of making report or entry of the vessel, pursuant to law, shall, in addition to the other matters required to be reported by law, deliver and report to the Collector of the district in which such vessel shall arrive, a separate list of all Chinese passengers taken on board the vessel at any foreign port or place, and of all such passengers on board the vessel at that time. Such list shall be sworn to by the master in the same manner as directed by law in relation to the manifest of cargo, and refusal or neglect of the master to comply with the provisions of this section shall receive the same penalties, disabilities and forfeitures as are provided for a refusal or neglect to report and deliver a manifest of the cargo.

Sec. 4. That the amount of the several penalties imposed by the foregoing provisions shall be liened on the vessels violating those provisions, and such vessels shall be libelled therefor in any Circuit or District Court of the United States, where such vessel shall arrive.

Sec. 5. That nothing herein contained shall be held to repeal or modify any law forbidding the importation of coolies, or of females for immoral purposes, into the United States; provided, that no Consul or commercial agent of the United States, residing in any port from which any vessel taking Chinese passengers may take her departure, shall grant the certificate provided for in section 2,162 of the Revised Statutes for more than 15 Chinese passengers on any one vessel.

Sec. 6. That this act shall not apply to persons officially connected with the Chinese government, or any Embassy thereof, or to persons rescued from shipwreck during the voyage of and by the vessel seeking a harbor in stress of weather within the jurisdiction of the United States, or to persons who may only seek a temporary residence for educational purposes, and who shall have a certificate from the Chinese government for that purpose.

Sec. 7. That this act shall take effect from and after the first day of July, 1879, and the President of the United States shall immediately on the approval of this act give notice to the government of China of the abrogation of articles five and six of the additional articles of the treaty of June 18, 1868, between the United States and China, proclaimed February 5, 1870, commonly called the Burlingame Treaty.

Fuel Saving.

Talk to ninety-nine out of every hundred coal men about economy of combustible and it does not interest them, because they expect a learned treatise, or else a project to save a hundred dollars' worth of coal a year by putting up a two thousand dollar apparatus. This article is intended for the ninety-nine.

In order that combustion may be perfect, it is necessary that the fuel and the burning medium be intimately mixed; which cannot well take place unless the two are in the same physical nature. They must be put in contact at the temperature necessary to perfect combination; their contact must be somewhat prolonged to ensure this elevation of temperature, intimate mixture and perfect burning. The proportions of fuel and combusant (which is the best word we can find for the burning medium) should be exactly that which is necessary to the desired result of combustion.

We will talk first about a free-burning coal, having a composition by weight of

Pure carbon	65 kilos
Ash	5 "
Water (absorbed)	5 "
Tar	5 "
* Lighting gas	20 "
Total	100 kilos

* Making 27 cubic meters at 0° C.

The 20 kilos of gas have about the following composition.

	Kilos.	Cubic Meters.
H—Hydrogen	0.24	2.67997
C2 H4	14.16	19.81414
C4 H4	1.60	1.26475
CO	2.60	2.07858
NH3	0.50	0.64882
HS	0.20	0.12985
CO2	0.70	0.35407
Totals	20.00	20.97018

In this coal we may have the following combustible elements (counting tar as C4 H also):

Pure carbon	65 kilos
Tar C4 H4	5 "
Hydrogen (H)	0.24 "
C4 H4	1.60 "
C2 H4	14.16 "
Carbonic oxide (CO)	2.60 "
Sulphureted hydrogen (HS)	0.20 "
Total	88.80 kilos

Suppose that we could burn these elements perfectly, we could get, according to Favre and Silbermann, 803,779.6 calories for the 100 kilos. If we could utilize this heat perfectly we should be able, according to Regnault, to produce for each kilo of coal 12.618 kilos of dry steam at 1 atmosphere, or 12.041 at 15 atmospheres. It is very evident that we do not get these results in practice, as we are content to range up to 5 kilos, and seldom run over 4.

In about all the boilers now used we employ a naked fuel-bed and natural draft.

Thanks to these two we manage to lose nearly as much of the heat as is possible. In general, combustion in a grate with natural draft is not chemically good. The fuel and the combusant are not in the same physical condition—one is a solid and the other a gas, and they get mixed they best way they can—which is not saying very much. Then very often there is as high as 30% or 40% of water carried over in the steam. But it is to the ordinary chimney that we owe most of our loss. If we take an ordinary boiler setting we find the following causes of loss of heat: 1st, excess of air owing to the use of a grate; 2d, the employment of a chimney; 3d, lack of a smoke consumer; 4th, cinders of unconsumed coal; 5th, badly built boilers; 6th, radiation from the fire-box and walls.

Grouping by species the combustible elements in our 100 kilos of sample coal, we find:

Carbon	82.39143 kilos
Hydrogen	4.73462 "
Sulphur	0.18824 "
Total	87.31429 kilos

These need, to burn them thoroughly into CO^2, HO and SO^2, 257.77568 kilos of oxygen. There is 1.48571 kilos of this oxygen in the illuminating gas; so have 256.28997 kilos of oxygen required to be brought in from outside, as part of the air; and to furnish this requires 1114.30422 kilos of air. As a temperature of 0°C and with barometer at 760 mm this would occupy 861.797 cubic meters.

Now, with a grate and a natural draft it is not possible to admit just this quantity of air. The grate is an obstruction—the air does not circulate freely in the fuel bed; and hence we endeavor to increase the grate areas and quicken the draft. We generally allow space enough for double the requisite quantity of air. The gases enter the base of the chimney at temperatures, running up as high as 500° C. (=932° F.) in the case of metallurgical furnaces—not so high in the case of ordinary boilers, suppose we say 370° C. =572° F.

The caloricity of air is, according to Regnault, in weight, 0.22727 at zero. Applying this to our case, and supposing that we introduce an excess of 1114.30422 kilos, and that it escapes at 500° C., the loss of heat will be 132.195 calories, or 16%. In puddling furnaces and express locomotives it often passes this on account of the sudden introduction of great currents of cold air.

The loss from chimney draft alone is 25% of the heat furnished by the combustion of the coal. Even supposing that the combustion was complete and without excess of air, the calculation applied to the foregoing figures gives for the gases burned the following composition:

Nitrogen of the air of combustion	858.01425
Carbonic acid of combustion	302.10091
" " of the lighting gas	0.70000
Water of combustion	42.01158
Hygroscopic water	5.00000
Ammonia of the lighting gas	0.50000
Sulphurous acid, SO^2, of combustion	0.37648
Total	1209.30422

The calorific equivalent of these gases counts up to 288.25532, and supposing them to escape at 500° C., the total heat carried off by them amounts to 144.12766 calories, or 18%, even supposing an exactly perfect combustion.

The loss in smoke is considerable. The coal and air cannot be intimately mixed, and hence combustion is not perfect. The "smoke" may be *colorless* and yet contain considerable quantities of combustible gases—that which blackens smoke is merely impalpable carbon mechanically carried over. Dehette states the loss from smoke as 9% at least, and analyses have shown sometimes as high as 24%. Experiments at Mulhouse give 15%; Ebelmen found 7%; Siemens found 40%. We might say 20% without very far overshooting the mark.

The loss from cinders, that is, unburned coal, varies. In the case of locomotives—where they are not recovered—it is very considerable. In metallurgical furnaces it is also large—frequent stirring causes the particles to free—and in burning below they cause great discomfort to the puddler. In experiments at Cherbourg, Tresca and Silbermann found 25% of cinders; but we are hardly justified in saying that the loss here will run over 15%.

In calculating the heating power of our coal, we have adopted for the calorific power of hydrogen 34,462; but this is the heat given out in burning hydrogen into water. Now this water has to be vaporized at an expense of heat equal to at least 29,102 calories, (48 kilos × 606.5, which is the latent heat of vaporization of water). These 29,102 calories represent 3.6% loss.

We have still another loss, that due to radiation, melting of ashes, etc.; but we will not count this now. We have already found the following percentages of loss:

1. Excess of air	16 %
2. Chimney	18 %
3. Smoke	20 %
4. Cinders	15 %
5. Vaporizing 48 kilos of water	3.6%
6. Radiation, etc.	(?)
Total	72.6%

We may say then 73% of loss by the use of a grate and natural draft. To obviate this, we find that there are employed: 1. Rocking grates. 2. The introduction of hot or cold air at various points. 3. Smoke-consuming fireplaces with steam jets over the flame, on the coal, or in the chimney. 4. "Gas furnaces."

The first series are in many cases excellent, but are complicated. The second have given good results in some cases; but many of them cause the introduction of *too much air*, and only exaggerate the first loss. The third gets a little nearer the bottom of the question. They aid the mixture of the gaseous matters; but the steam injected absorbs heat by its partial decomposition, increases the loss through the chimney, and costs too much. One smoke consumer (Thierey's) saves 10%, but it costs in live steam, enough coal to count up to 8%, leaving an economy of only 2%.

Of gas furnaces, the best known is that of Siemens. The generator is not "blown," the heat produced by the oxidation of the carbon is lost, and the gases produced lose their heat before coming to the regenerator. The heat set free by the first transformation of the carbon is 160,745 calories, or about 20% loss. There is a certain quantity of tar deposited in the passages. Supposing that its sale pays for taking it out, we have a loss of heat of $11,588 \times 5 = 59,290$ calories, or 7.4%. The radiation from the furnace is not saved, and it is very considerable in this system. Krans states it at 27,750 calories, which is in our case, 3.5%.

Being of natural draft, the thickness of combustible is limited. With a forced combustion, the thickness of the bed could be increased and the carbon completely oxidized. The first draft causes a loss of heat equal to 20%. The gases escape from the chimney at 200° C. (392° F.) and higher, and we might place the loss from the second draft at 10%. The loss from incomplete combustion is lessened and may be stated at 5% instead of 10%. The vaporizing of the 48 kilos of water takes place here, of course, with its attendant loss. We might then consider the useful effect of the gas furnace diminished by the following losses:

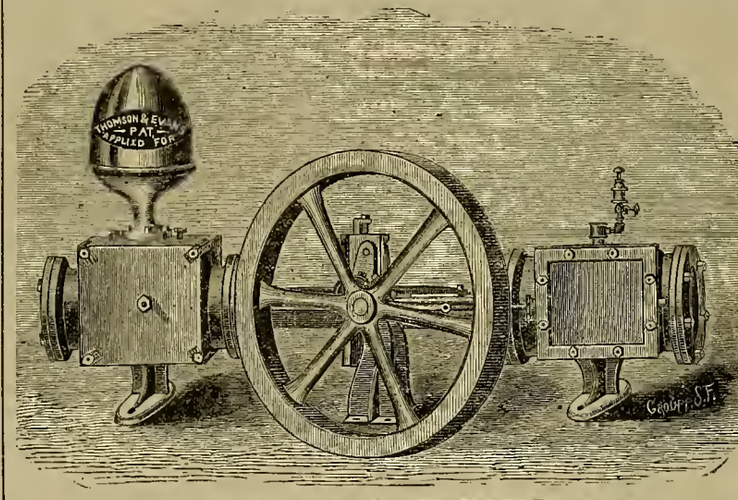
Oxidizing the carbon	20.0%
Waste of tar	7.4 %
Second draft	10.0 %
Smoke	5.0 %
Radiation	3.5 %
Vaporizing 48 kilos of water	3.6%
Total	49.5

Or nearly one-half. As the ordinary systems waste 73.5, we have its saving over the other 24% of what the coal ought to do, and its useful effect $24 \div 26.5 = 90.56\%$. We can, however, see a wide field for inventive genius.

Thomson & Evans Pump.

We saw this week at the machine shop of Thomson & Evans, 112 Beale street, a new water cylinder for the large steam pump of the Empire coal mine, at Mount Diablo. The water cylinder is 7⅜ inches in diameter and 3 feet stroke, and the steam cylinder 18-inch diameter. This pump is intended to lift the water 600 feet at one lift.

The water cylinder end of the pump is somewhat peculiar in the arrangement of the valves. The valve plates are separate from the chests, and made to fit in between the suction pipe and valve chests so that the whole plate may be removed by taking out a few bolts. It is then only a few minutes work to remove the plates and put in new ones when they wear. Hand holes are also made in the chests through which any of the valves may be taken out separately.



THOMSON & EVANS CRANK AND FLY-WHEEL PUMP.

The valve slides on a spindle which screws into the spider, there being a spring on the spindle, back of the valve. The outer ends of the spindles have a handle by which they may be unscrewed when the valves need facing up or new washers. Separate valves are kept on hand and may be put in in a few minutes and the old ones removed. This construction has been found necessary, as the water in the mine is very bad and eats out the valves and plates very quickly. These pumps were made with the object in view of being able to quickly change the valves and plates, as it is so frequently necessary.

They manufacture at this shop, a style of crank and fly wheel pump of the type illustrated on this page, which has become a favorite for boiler feed for steamboats, etc. The yoke is solid, the piston rod for both chambers being in one piece. Usually the yoke is open and the rod in two pieces so that a certain amount of play is allowed after the pump is used a short time. With this, however, the yoke is solid and the pump always runs true without any chance of getting out of order. The valves are so arranged as to be easily accessible for repair. Mr. Watson, chief engineer of the California Sugar Refinery, is running one of these pumps 1,800 feet from the well from which the supply is drawn, and it pumps 100,000 gallons of water a day, to a hight of 60 feet. He says, as regards economy and durability, it is superior to any direct-acting pump. This one has a 10-inch steam and 5-inch water cylinder, with 18-inches stroke. A number of these pumps are used on steamers on the bay. On the tugs they put a pinion on the shaft and gear wheel on the gipsy, and by means of the pump haul in hawsers and light loads on the gipsy. They are also used for wrecking pumps, etc.

A COMMITTEE of the Illinois Legislature has decided to report that the rates of the Pullman Car Company are not exorbitant, as the dividends are only 8%.

THE rainfall so far this season is 11.40 inches.

The Dead Mining Towns and What They Teach.

John Muir, the mountain climber and pleasant writer upon what may be seen at these high altitudes, has, in the *Bulletin* of recent date, a characteristic letter wherein he describes the dead towns and mining camps met with in his peregrinations through the State of Nevada. The defunct are many and melancholy to behold, as being the woful evidences of a vast amount of energy misapplied and capital misspent. And it would be well if these monuments of waste and folly were confined to Nevada, which they are not. We find them throughout the entire mining region of the Pacific coast. They exist in Utah and Colorado; in Idaho and Montana; in Arizona, the youngest, and in California, the oldest of our mining countries; though it is but fair to say, that fewer of them are to be found in this State than anywhere else. We have here, to be sure, many of these nearly deserted and much dilapidated towns; places that were once populous, prosperous and musical with the hum of business. But as a general thing they were not, like the towns of which the mountain climber speaks, premature and uncalled for—brought into existence through a forced and unnatural growth. They were built for the accomodation of the business pertaining to and of the miners employed in the diggings about them. When these latter were exhausted, the miners left, business ceased, and these towns went to decay. But they had subserved the end for which they were built, and when they perished, no one was disappointed, and no one specially suffered. The exceptions to this rule here in California, are found in the towns of Meadow Lake, Silver Mountain, Panamint and a few other less signal instances.

In Nevada, John Muir might have added a good many notable examples to the number of the "late deceased," mentioned in his letter to the *Bulletin*. The empty towns and the well filled graveyards are not confined (and he intimates as much) to the Toiyaba range, the Schellburn canyon and the localities about Treasure Hill. They stand on the hill slopes, sit in the deserts and look out from the mouths of the dark ravines everywhere over that whole country. They abound in fact, as we said before, in all the States and Territories west of and adjacent to the Rocky mountains. Even in the gloomy woods of Washington and British Columbia we encounter them. Whatcom, deserted almost as soon as it was built, sits a ruin on the beautiful waters of Puget sound. Port Douglas, once the hopeful entrepot for the Upper Frasier river country, is now almost without an inhabitant, while Hope, Yale and Langly, at one time places of considerable size and very great expectations, are reduced to almost the same condition. Arizona, as a mining country, being so comparatively young, it might be thought would lack these examples of superannuation in youth; yet she has them too. La Paz is not; Gila City has outlived its usefulness, and Lyonsville has been extinguished, to say nothing of the Aztec remains that relate to the doings of another race and an earlier day. They are, indeed, everywhere all too numerous, these evidences of mistaken enterprise and capital wasted—these monuments of illusive hopes, vain plantings and unrequited toil.

But sad and numerous as they are, these ruins scattered over the great interior wilderness, they represent but one aspect of the case. There are other ruins behind these even more deplorable, and of which they are only the outward exponent. There is the financial ruin that so much wasted means and profitless expenditure have lead to. There is the ruined credit of the merchant, the farmer, and the manufacturer; the ruined hoard of the laboring man; the ruined deposit at the safety bank; and the general ruin worked to the gatherings of all classes of the community, for all have been made to contribute of their means towards this great outlay.

Without censuring the men who were chiefly instrumental in causing so great a misapplication of money, it having been in large measure the result of an ignorant over-zeal, it would not be out of place to remind these parties when they upbraid the community, as they often do for their backwardness in contributing towards the development of the mines, how very liberal these contributions have already been, and to what poor purpose they have sometimes been expended. Let the prospector, claim holder, and the promotors of mining schemes in general, remember how badly investors in this class of enterprises have heretofore fared, and seek to diminish the chances of their loosing when applying to them for money aid in future.

On the other hand it should be recollected that while so many of these early projects came to grief, it does not follow that the mines which they were designed to open up were worthless or otherwise in fault. Many of the districts that, under the first repulse, were abandoned, have since, under a wiser application of means and through better directed and more persistent efforts, show themselves to be rich in mineral wealth, some of them being now among the most productive on the coast. The mistakes that lead to their abandonment resulted mostly from want of experience. They were incidental to the times and scarcely avoidable. With our changed conditions, they should no longer occur, or if they do, should not be so readily condoned as in times gone by.

FOREIGN PATENTS

FOR PACIFIC STATES INVENTORS

ARE SECURED IN MUCH LESS TIME,

—BY—

DEWEY & CO.,

AT THE OFFICE OF THE

Mining and Scientific Press,

THAN THROUGH ANY OTHER AGENCY.

Established in 1860,

THIS FIRM CAN BE RELIED UPON

—AS—

Honest, Competent, Permanent,

ALL OF WHICH POINTS ARE IMPERATIVELY REQUISITE IN ATTORNEYS, FOR THE INTERESTS OF THEIR APPLICANTS FOR PATENTS IN DISTANT LANDS.

Our Associates and Correspondents are the Best Practitioners in every country where Patents are granted.

For Foreign Patents no model is required, as a rule, except in Canada. The Specifications and Drawings of the American Patent, if complete and perfect, will suffice for us to prepare the case. In Great Britain and other countries we apply for patents in the inventors' own names, thus avoiding their being published to the world in the name of a foreign agent, as is usual through other and less painstaking agencies.

Frequently several inventions, covered by different patents in the United States, on the same subject, can be skillfully combined in one patent in foreign countries, when well understood by intelligent attorneys.

As the privileges of our inventors are cut off in *some* countries, and curtailed in others, if not applied for soon after the issue of the U. S. patent, we advise inventors whose patents will be valuable in various populous civilized countries, to lose no time in applying for patents whenever they intend to obtain them for themselves or the benefit of others—with their own means or through the resources of those who are permitted to share the benefits. It must be remembered that the English (and some other important nations) invite the early introduction of inventions into their realms, by offering patents to the first *introducer* (which means the first *applicant*), without regard to the rights of the *actual* inventor, who has no after recourse.

For important inventions it is best to apply for foreign patents at the time of application for or before the issue of the U. S. patent.

Term of Patents in Foreign Countries

COUNTRIES.	PERIOD OF YEARS GRANTED, ETC.
Australian Colonies: Victoria	14 years in successive periods, 3, 4 & 7 yrs
Tasmania	14 years in successive periods, 3, 4 & 7 yrs.
New South Wales	7 to 14 years
Queensland	7 to 14 years
New Zealand	Full term, 14 years
Austria	15 years, by annuities.
Argentine Republic	25 years or more, determined by gov't.
Belgium	20 years by annuities.
Brazil	5 to 20 years
Canada, (including British Columbia)	14 years
Chile	25 years or more, determined by gov't.
Cuba	5, 10 and 15 years
Denmark	5 to 20 years, at the option of government.
England	14 years, in successive periods, 3, 4 & 7 yrs.
France	15 years, by annuities.
German Empire	15 years
Italy	12 years, by annuities.
India	14 years, 5 copies, specification required.
Mexico	Full term, 20 years
Norway	5 to 10 years, at the option of gov'm't.
Portugal	Importation 5, Invention 15 years
Peru	25 years or more, determined by gov't.
Russia	Importation 1 to 6 yrs. Invent'n, 3, 5, 10 yrs.
Spain	Importation, 5 yrs, Invention 5, 10, 15 yrs.
Sweden	3 to 5 yrs, at the option of government.

We have the Foreign Patent Laws, Foreign Patent Reports, and other valuable and assisting documents, for ready reference in our MINING AND SCIENTIFIC PRESS Patent Agency Library—the most complete Patent Library on this side of the Continent.

The cost of patents in any one or more of the above countries will be furnished on application to us.

Any further information regarding the time within which patents must be worked in any foreign country, time of payment and amount of annuities for patents in any of the above countries, will be cheerfully given on application.

Full particulars regarding any countries not named above, will also be given when desired.

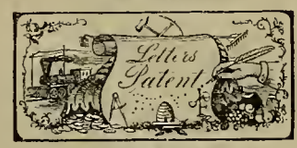
REGISTER YOUR

TRADE



MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

DEWEY & CO., Patent Solicitors,

No. 202 Sansome Street, S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, $7.5

MINING LAWS AND DECISIONS.

Copp's Hand Book of Mining Laws.

In this little work is given the United States Mining Laws and Instructions. Also, a digest of the decisions under the laws, by the Secretary of the Interior and Commissioner of the General Land Office.

Forms are given for making out notice of location proof of labor, application for survey, and in fact all the blanks a miner needs.

There is also a list of all the mines for which U. S. Patents have been obtained from July, 1866, to August, 1877, with location, township and range.

A handy companion for miners. Price $1, post paid. Address

DEWEY & CO.,
202 Sansome Street, S. F

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,

North Bloomfield, Nevada Co., Cal., October 1st, 1878.

Continued from Page 117.

ent crosscuts are without any material change. We have put in 12 new sets of timbers in south compartment of the hoisting shaft. The timbers are in a very rotten state and will have to be replaced for at least 150 feet.

EUREKA DISTRICT.

JOTTINGS.—*Sentinel*, Feb. 15: It is reported that a rich and extensive strike has been made in the Jackson mine. The Eberhardt & Aurora mine is now being worked on tribute by Messrs. Green, Suider and others, and is looking well. The ore is of a very high grade, but the casing of the ledge is so hard that it is almost impossible to break it in any great quantities. Mr. Robertson, of the Baldy Sour mine, has let a contract to run 80 feet of a drift from the bottom of the shaft, which has heen taken by Messrs. Whealan & Kenney. The Stafford company are prospecting their mine, and are opening a fine body of ore. Tim Shine has a streak of ore from two to three inches thick, John Dick is prospecting his mine, working three men.

ELY DISTRICT.

RAYMOND & ELY.—Pioche *Record*, Feb. 8: There has been hut very little work done on the 1300 level; the ledge has not been crosscut, but shows very well where it has heen broken into. The 1400 level has two crosscuts only about 25 feet apart; the ledge seems to be broken up a little at this point from the influence of a cross-course that runs through at this point. The winze is now down 50 feet below the 1400 level, in good sinking ground, and all heavily charged with mineral. The raise from the 1200 level is showing finely; four feet drill hole put in shows assays of $120 per ton. Mine and mill running finely; mine producing about 200 tons of ore per month, assay value, $200 per ton.

REESE RIVER DISTRICT.

MANHATTAN ITEMS.—*Reveille*, Feb. 15: During the past 10 days there was reduced 162 tons, the assay value of which is $33,002.13, of this amount $13,861.29 was from custom ores and $19,140.84 from the Frost and Curtis shafts. The battery since the 10th instant has been run 12 hours per day. The 517 west drift, of the Curtis shaft, contains some good ore in places; a crosscut has heen started in the foot wall to prospect the 560. The 560 stope continues to produce about the same quality of ore from the several different strata that are being worked. The drifts being run east and west from the 600 west crosscut both contain good ore, that on the east side being much the best. A chute is being raised from this level to connect with the 560 level. The 825 stope is opening out very well and considerable good ore could be extracted were the level well ventilated. The ore at the 770 and 870 levels, of the Frost shaft, does not afford any margin when worked on day pay; and the entire mine is now worked on trihute. They are now opening out on a body of ore below the 600 west drift of the North Star shaft on the Allsopp ledge.

Agricultural Works.

This week we had the pleasure of being shown through the new agricultural works and foundry of Byron Jackson, on the corner of 6th and Bluxome streets, in this city. Mr. Jackson, whose new and valuable improvements in agricultural machinery have received frequent mention in our previous issues, first opened a machine manufacturing business at Woodland, in 1872. The works there were smaller than those now occupied, and were intended chiefly to produce the new inventions in separators, forks, etc., of which he holds the patents. His improved machinery met with immediate approval, became popular, and his business rapidly enlarged. One invention leads to another, and each improvement requires new and special machinery. This, together with the isolated position of Woodland as regards shipping facilities, the profit to be made by purchasing raw material in the city, together with the desire to be nearer to his customers, about a month ago led to the transfer of the works to their present situation.

The building is 112x125 on the ground plan, and is two stories high. The first thing that strikes the eye on entering, is the brightness and neat arrangement of the interior. The great number of windows allows an abundance of light to enter, a thing not commonly found in such places. The engine is situated in the center of the building, and the gearings and connections are so arranged, that the running of any one part of the machinery can be accomplished without necessarily keeping the other parts in motion. This of course makes a great saving in the expenditure of power, and also in the wear and tear on the machinery.

The Jackson "Feeder and Elevator" has already received notice in these columns, and is withal, too well known to need description here. We will only say that it possesses the two great virtues of simplicity and durability. It, together with the "Jackson Light-Weight Horse Fork," are made specialties by the house, though all sorts of light agricultural machinery are manufactured to order. The horse-fork above mentioned attracts the eye at once, and especially of those accustomed to the heavy clumsy forks now in use. It is only half their weight, yet is equally strong and durable. It is constructed of a light frame, the head being formed of two pieces, one on each side through which the tines pass, the tines, together with a light iron brace from each tine to the frame, lock the parts firmly between them. The strain is brought to bear straight with the grain of the wood, avoiding all twisting motion. The whole weighs about 35 pounds.

The works are not running in full blast, a large part of the machinery having yet to be placed in position. The common force of hands when all is in running order is 30. At present no new separators are manufactured, but simply old ones modified and supplied with the new patent feeders, elevators, shoes, etc. As soon as the present works are fully in running order, Mr. Jackson expects to commence making entirely new machines of his own patent, his facilities for so doing covering every part of the operation from the woodshop to the foundry.

News in Brief.

THE Egyptian army is to be reduced to 10,000 men.

AN alliance of Eastern trunk lines is strongly rumored.

A GREAT deal of stock is faring badly in southern Oregon.

THERE is a deficit in Hungarian finances of 24,000,000 florins.

TYPHUS fever is raging in Paris, especially among the soldiers.

CONGRESS is voting away money by appropriations, in millions.

THE Roman Papacy is bankrupt and cannot pay its hishops.

A FREE trade coalition is being formed by the German Reichstag.

FIVE HUNDRED fresh communists are to be pardoned in France.

THE continued drouth is liable to cause another famine in India.

A FARMER near Cuffey's Cove has begun the culture of flax.

ARIZONA has come to the front as the loosest divorce State in the Union.

THREE HUNDRED AND FIFTY Chinamen were shipped homeward this week.

THE Congressional Deficiency Appropriation bill aggregates $2,500,000.

A SEVERE shock of earthquake was felt at Hollister, on the 13th inst.

GAME has become scarce in Oregon, through its indiscriminate slaughter.

A WHALING station is to be established at Little River, Mendocino county.

THE Indians are rising in Alaska and massacreing the white inhabitants.

THE remains of the late Bayard Taylor will shortly arrive in New York.

Two men were blown to atoms by a premature blast explosion in Virginia City.

THE Chinese Emperor has 100,000 subjects in California capable of hearing arms.

HOT water has been turned into the Sutro tunnel and the working force discharged.

LARGE numbers of cattle are starving to death in Nebraska, the feed being covered hy snow.

A SEVERE snow storm is raging on the upper Columbia, and the river is closed by the ice.

DALLAS, Texas, talks of following the example of Memphis, and throwing up her municipal charter.

THE Czar has issued a manifesto declaring definite peace with Turkey, and the troops have been ordered home.

MACHINERY HALL, Centennial grounds, Philadelphia, originally costing $800,000, was sold at auction recently for $24,000.

STATISTICS show that the number of cigars annually consumed in the United States is 40 for each man, woman and child, in addition to two pounds of tobacco each.

AN Oregon Chinese cook put strychnine in the coffee he had made for breakfast; was detected by the men, forced to drink a large quantity of it and died from the effects.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Griffith Consolidated Mill and Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Diamond Springs Mining District, El Dorado County, California.

Notice is hereby given, that at a meeting of the Board of Trustees, held on the 21st day of January, 1879, an assessment (No. 1) of twenty cents (20c) per share was levied upon the Capital Stock of the Corporation, payable immediately to the Secretary, at the Office of the Company, Room 48, 330 Pine Street, San Francisco, California.

Any Stock upon which this Assessment shall remain unpaid on the 26th day of February, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, March 26th, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees. GEO. M. CONDEE, Sec'y.
Office, Room 48, 330 Pine Street, San Francisco, California.

Office Wide Awake Prospecting and Mining Company.—No. 232 Sutter Street, San Francisco, Cal., February 1st, 1879. Location of works, Picket-Post, Pinal County, Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the first day of February, 1879, an assessment (No. 6) of four cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 2, No. 232 Sutter Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fifth day of April, 1879, to pay the delinquent assessment, together with the cost of advertising and the expenses of sale. By order of the Board of Directors. C. HILDEBRANDT, Secretary.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the fourth day of February, A. D., 1879, an assessment (No. 7) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the eleventh (11th) day of March, A. D., 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Tuesday, the eighth day of April, A. D., 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.
R. N. VAN BRUNT, Secretary.
Office, Room 6, No. 318 Pine Street San Francisco, Cal.

OFFICE OF THE

GIANT POWDER COMPANY,

San Francisco, February 15th, 1879.

To the Mining Public.

The fact that a new Company has just been organized in this city for the avowed purpose of making and vending a Dynamite Powder called Vulcan Powder, which Powder has been for over a year past and is at this moment under injunction from the U. S. Circuit Court at the East and is soon to be proceeded against on this coast, renders it proper and necessary that this Company should make a statement concerning the present position of its patent litigation, to the end that no person should be induced, through the lack of information, to engage in a business which must shortly bring him before the Courts to answer to an infringement suit.

The public is already aware of a recent decision of the United States Supreme Court on appeal in the case of the Giant Powder Company vs. the California Powder Works, and has recently seen various newspaper articles in the interest of infringers upon the Nobel Patents, calculated to create a false impression as to that decision.

The decision in question was simply against the validity of two unimportant Reissues, Nos. 4818–10, both from an old Patent, No. 50,617, issued in 1865, long prior to the Dynamite invention, which latter invention was first patented in the United States by original Patent No. 78,317, issued May 26th, 1868, from which Patent No. 5,790 is a Reissue, and not, as has been falsely stated, a Reissue of the old Patent of 1865.

This Dynamite Patent No. 5,799, consequently has no connection whatever with the old Patent of 1865, nor with its Reissues, and was not in anywise impaired by the above referred to decision of the U. S. Supreme Court; on the contrary, by that decision the case was sent back here for trial, and the defendants were ordered to appear and answer to the suit of this Company under said reissue No. 5,799, which they must do in due time.

The Dynamite Patent (5,799) is the vital Patent of all the Nobel inventions. It is the Patent under which all the late injunctions have issued from the United States Circuit Courts at the East. Under it two injunctions have already been issued there, and are to-day in force against the same Vulcan Powder, made by the same person who is to be the manager of the new Company here. In every case yet decided by the Courts, this Patent has been fully sustained. Under it the following injunctions have been issued:

CIRCUIT COURT OF THE UNITED STATES, DISTRICT OF MASSACHUSETTS.
THE ATLANTIC GIANT POWDER COMPANY vs. GEORGE W. MOWBRAY, ET AL.
Before Shipley, Judge.
Bill in equity for making and selling Mica Powder.
Decree October 5, 1877, for perpetual injunction.

CIRCUIT COURT OF THE UNITED STATES, DISTRICT OF MASSACHUSETTS.
THE ATLANTIC GIANT POWDER COMPANY vs. GEORGE A. GOODYEAR.
Before Shipley, Judge.
Bill in equity for selling Vulcan Powder.
Injunction granted December 21, 1877.

CIRCUIT COURT OF THE UNITED STATES, DISTRICT OF MASSACHUSETTS.
THE ATLANTIC GIANT POWDER COMPANY vs. GEORGE W. TOWNSEND.
Before Shipley, Judge.
Bill in equity for using Vulcan Powder.
Injunction granted December 21, 1877.

CIRCUIT COURT OF THE UNITED STATES, DISTRICT OF NEW JERSEY.
THE ATLANTIC GIANT POWDER COMPANY vs. THE NORTH JERSEY IRON CO., ET AL.
Before Nixon, Judge.
Bill in equity for using Vigorite Powder.
Injunction granted April 30, 1878.

CIRCUIT COURT OF THE UNITED STATES, SOUTHERN DISTRICT OF NEW YORK.
THE ATLANTIC GIANT POWDER COMPANY vs. THE NEPTUNE POWDER COMPANY.
Before Blatchford, Judge.
Bill in equity for making and selling Neptune Powder.
Injunction granted May 20, 1878.

CIRCUIT COURT OF THE UNITED STATES, SOUTHERN DISTRICT OF NEW YORK.
THE ATLANTIC GIANT POWDER COMPANY vs. THE MINER'S POWDER COMPANY.
Before Blatchford, Judge.
Bill in equity for making and selling Vigorite Powder.
Injunction granted May 20, 1878.

CIRCUIT COURT OF THE UNITED STATES, WESTERN DISTRICT OF PENNSYLVANIA.
THE ATLANTIC GIANT POWDER COMPANY vs. VALENTINE LEARY, ET AL.
Before McKennan, Judge.
Bill in equity for using Neptune Powder.
Injunction granted June 10, 1878.

CIRCUIT COURT OF THE UNITED STATES, SOUTHERN DISTRICT OF NEW YORK.
THE ATLANTIC GIANT POWDER COMPANY vs. ANDREW J. PARKER, ET AL.
Before Blatchford, Judge.
Bill in equity for making and selling various nitro-glycerine powders.
Injunction granted September 13, 1878

CIRCUIT COURT OF THE UNITED STATES, SOUTHERN DISTRICT OF NEW YORK.
THE ATLANTIC GIANT POWDER COMPANY vs. WILLIAM AGAR, ET AL.
Before Blatchford, Judge.
Bill in equity for making and selling Potentia Powder.
Injunction granted September 13, 1878.

In addition to the foregoing several other important cases have just been argued and submitted, decisions upon which will be forthcoming very shortly.

Having placed the foregoing facts before the public, any person who may hereafter engage or become interested in making Nitro-Glycerine Powder in infringement of the Nobel Patents, will do so with his eyes open, and will have no cause of complaint when the Giant Powder Company moves, as it very shortly will do, to establish its rights on this Coast.

It may be well to add that the Giant Powder Company has no intention whatever, upon the complete establishment of those rights, to extort high prices for its Dynamite, but will continue to furnish Powder to the mining public at moderate prices.

The foregoing is published in pursuance of a resolution passed at a special meeting of the Board of Trustees, held this 15th day of February, 1879. By order of the Board.

The Giant Powder Company,
By its Secretary, H. PICHOIR.

The "California Legal Record."

The ONLY WEEKLY containing all the decisions of the Supreme Court of California,

(The ONLY COMPLETE continuation of the S. F. *Law Journal*.)

Published every Saturday, in 8 vo. size—like the California Reports—contains EVERY DECISION of the Supreme Court, as fast as rendered, with a syllabus and statement of facts, and other important legal matter. The volumes commence on the first of October and April each, and have a full index for reference and binding.

REDUCED PRICE, only $5.50 per year, or $3 per volume of six months. Remit by Postal Order or Registered Letter, specifying what date or number to commence. Back numbers furnished. Sample numbers sent free. Address,

F. A. SCOFIELD & CO., Publishers and Prop's.
No. 603 Washington street, San Francisco, Cal.

Cheerfully Recommended.

CHEROKEE, Sept. 8th, 1878.

DEWEY & Co.—*Gentlemen:*—Having received my Letters Patent for improvement in vehicle wheels, I consider it a duty I owe your firm to tender my sincere thanks for the interest and pains you have taken in the prosecution of the case. I shall cheerfully recommend your firm to such as may need your services. I remain yours,

Very Respectfully, WM. THUNEN.

OFFICE OF THE

VULCAN POWDER COMPANY,

San Francisco, Feb. 17, 1879.

To the real mining public it is unnecessary to state that Vulcan Powder is not new to this coast, having been well and favorably known and largely used by many of its leading mines for over two years.

Vulcan Powder in the past has been the means of assisting the Mining Industries of the Coast in this, that miners can now get better Powder for less money than formerly from a Company which has attempted to monopolize this business, claiming rights entirely outside of either its patents or reissues. Now that the Vulcan Powder Company—joined by prominent mining men, themselves among the largest consumers of Powder on the Coast—has been incorporated, it is perhaps natural that the would-be monopolists should again renew the idle threats with which they have from time to time deluged the mining community, but with what result is best shown by the constantly diminishing sale of their boasted "High-Explosive."

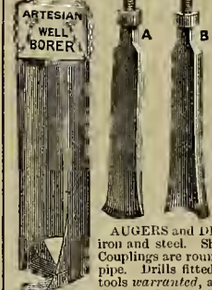
The following are the FACTS as to their infringement suits against Vulcan Powder in the East: In May, 1875, in the Circuit Court for the Southern District of New York, General Newton, the United States Engineer in charge of the "Hell Gate excavations," and the same Mr. R. W. Warren, now Manager of the Vulcan Powder Company, were sued as co-defendants for making and using the same Vulcan Powder by the Atlantic Giant Powder Co. A decision on this, the main case, brought against Vulcan Powder, was ardently desired by us. But when the case was placed on the calendar, the Atlantic Giant Powder Company WITHDREW THEIR COMPLAINT. The decisions referred to in recent advertisements as against Vulcan Powder, had no bearing on the real issue, else why has this Company not been DIRECTLY attacked long ere this?

As regards the recent decisions of the United States Supreme Court, which the Giant Powder Company says is "calculated to create a false impression," we will say: The Reissues, Nos. 4818-19, which were declared VOID by the decision mentioned, are for the COMPOUNDS WHICH WE ARE MANUFACTURING. Reissue No. 5799 is for a compound (the so-called Giant Powder) WHICH WE NEVER HAVE AND NEVER INTEND TO MANUFACTURE. This is the whole case in a nutshell. We leave all intelligent persons to draw their own conclusions.

We hereby notify all dealers and consumers of Vulcan Powder that we will hold them harmless against any suit the Giant Powder Company may bring against them, and agree to pay all costs of litigation so incurred.

The mining public knows, judging from past experience, that, notwithstanding the promise of *would-be monopolists*, never to "extort high prices," its *only* security against "high prices" is in patronizing the competing company. This matter of the price of Powder is too important to be left to the *sense of justice* of a corporation which claims an oppressive royalty on the Powder business of this Coast.

Vulcan Powder Company,
RALPH L. SHAINWALD,
Secretary.



ARTESIAN AND SURFACE Well-Boring TOOLS.

Manufactured by the Rust Well Auger COMPANY, OF MACON, MO.

AUGERS and DRILLS from best wrought iron and steel. Shafting is 2-inch gas pipe. Couplings are round plugs fitted inside the pipe. Drills fitted for rope or pole. All tools *warranted*, and sold for less money than can be got elsewhere.

Send for Circular. O. RUST, Macon, Mo.

Prompt Attention to Business.

AURORA, Nev., Dec. 7th, 1878.

MESSRS. DEWEY & Co., S. F.—*Dear Sirs:*—I acknowledge the receipt of my patent per express this morning, and am obliged for same. I do not know what to say to you regarding your prompt attention to business, but will say to my friends what I cannot say to you. Many thanks is what you will get from Yours truly, C. W. LANE.

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

Ingersoll Rock Drills.

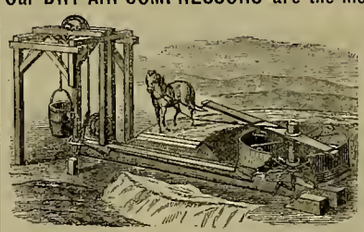
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

Hughes' Fog Signal Compass.

A Ready Meane of Avoiding Collision of Veseele in Foggy Weather.

Capt. William Hughes, who has been for many years captain on the line of ferry eteamers bctwcen thie city and Oaklaud, and who has plenty of opportunity for knowing the difficulties of finding the way from wharf to wharf in thick weather, has devised a fog eignal compass, with which by very eimple means, danger of collision may he avoided. Numerous attempte have bcen made to perfect a codo of signals, by which veseels can determiue the position or couree of other veseels in a fog, but moet of them are either too complicated or otherwise impracticable. Capt. Hughee has invented a system which eeeme perfectly eimple, and in which the course to pursue ie as plain as the compaes poiute, and, iu fact, is printed on the compass.

The difficulty is usually to tell what course the other vessel ie on when two are approaching each other in thick weather. Collieions frequently occur between eteamers even when the respective captains kuow of the proximity of the veseels by the eound of the whietles. In foggy weather the *direction* of eound ie difficult to determine, and while it may appear to come from off the port bow for instance, it may really be off the etarboard bow or dead ahead, and the actual position or course of tho other veesel may not he determined until too late to avert collision. This was the caee in the recent collieion between the *Alameda* and *El Capitan* in San Francieco bay. If, however, the mastere could indicate to each other by any simple eetablished code of eignale the course of each veseel, euch collisione could be avoided.

It ie thie that Capt. Hughes' eystem doea. He makes the code of eignals unmistakeable in its character, and eimple to carry out hy means of an improved compass card, wbich is used ou any compaee, and in no way changes any of the exieting conditions of pointe of compaee or Government rules. A fac simile of this card is ehown in the engraving.

On the outer circle of the compass card are the usual marks and letters indicating the pointe of compass. Just inside of this outer circle ie another circle, in which ie printed a eeries of arbitrary numbers, whicb correspond to definite points of the compass, eaid figures beiug printed on the eame place on all carde alike, with relation to the eame pointe.

We append a fac eimile of the key from which, even those not familiar with nautical mattere, may understand bow the eystem works :

Key to Captain Wm. Hughes' Fog Signal Compaes.

1 WHISTLE STARBOARD.
2 WHISTLES PORT.

Distress Signal—A succession of single sounds.

The above ie on a eeparate card, whicb may be on the ineide of the cover of the compaes box or any convenient place where it and the compaee may be eecn at the eame time, and ie the key to tbe figuree on the compase card, which indicatee what eounde to make with whietle, bell or fog horn, to correepond with tho figures and points of compass on the card. It ie only neceeeary to look at the key once to understand it, as the numbers, etc., are all contained on the compass card.

The use of the compase may be underetood from the following examplee: Suppoee for instauce a veeeel is eteering due north in a fog, and the maeter wishes to indicate to another veseel the course he is on. Thie compase pointe north, and under this point on the compaee card are the figurce 212. He then eounde 212 by the whietle, in the manner indicated on the key, viz : two distinct sounde by the whistle, and then an interval ; then a eingle note followed by an interval ; and then two coneecutive notee, eaid eounds repreeenting the numerale 212. The master of the other veseel hearing the whietle sounded in thie way, looke at his compass for the corresponding number, which telle him that the vessel from which the eound comee ie eteering due north. Again, north by eaet, is indicated by the numerals 12, and by the sound of a eingle note followed by an interval, and then two consecutive notes. The course northeast by north is represented by the number 15, which is indicated by one einglo notc, and after an interval, five succeeive notes. All the different points of the compass have their respective figuree marked on the circle as described, and the key showe the method of sounding any desired one.

CAPTAIN WM. HUGHES' FOG SIGNAL COMPASS.

The sounde are made on the same principle as the fire alarm bell iudicates the district in which a fire has occurred, and directs the firemen which way to go. These sounds indicate to others which way the vessel, from which they come, ie going. The intervale of eounds are ehown very plainly on the key.

There is never any doubt which one to eound, for it is indicated on the compaes for any course the veeecl is eteering ; and the master of each veesel can tell which course the other ie pursuing.

In the center of the compass card is a circle having several phrasee printed with correeponding numbers to he used in the eame way. For inetance, the words "To etop her," are represented by the number 122, eounded by a single note, followed by an interval; then two notee and an interval, and then two more notes. "To back her," is represented by the numbere 222, and "At anchor," hy the numbers 223, which may be eounded in the manner described. These phrases repreeent that the veesel eounding the numbers is etopping, ie being backed, or ie at anchor, as the case may be. The "dietreee signal" is a eucceseion of sounds repeated rapidly. On another circle are printed the worde and figuree, "1, Starboard" and "2, Port," on oppoeite eides of the cards, which are the ueual eignals for eteamers to pase to etarboard or port.

These eound eymbole will indicate on dark nights or in foggy weather the poeition and couree of vessels, so that they may pass and repass without danger of collision, each knowing what the other ie doing and what couree he is on although not in eight.

The etarboard eignal (1) ie eounded at all timee in thick weather and when any approaching sound should be heard, the course ehould be immediately eounded as described to indicate the couree of the veeeel.

Thie code of eignale would prevent accidente from collisions in a fleet of veesele eailing in the eame general direction in company with each other, ae in the case of a war fleet. The recent collision between the war veeeels *Kœnig Wilhelm and Grosser Kurfurst*, when 300 livee were lost, might have been prevented could the course of the respective veseels have been determined by the other master. They were steering at an angle toward each other in a fog and collidcd. With a code of signale which would have indicated tbe couree, they would not have steered across each other, but the coureee would have been altered eo as to be parallel, or the veesele eteered at a slight angle away from each other.

This eyetem doee not in anyway interfere with any of the ordinary rules governing navigation, or alter the compass. The printed matter on the compass card is merely eupplemental, put there for immediate convenient reference, and because the eame conditione exist in all compasses alike. When vessele find that they are steering towards each other they can each alter the couree, which fact the other one immediately knows as the eignal ie changed to correspond, and collieions are avoided.

Thie eyetem is more fully perfected than any yet made public and has the merit of eimplicity as a guide for steamehips and eailing ehips steered by compass in foggy weather. Had it been in uee on our local ferry, the accident the other day would have been avoided, as the respective captaine could have told by their compasses that they were eteering at an angle toward each other, and no matter where they each thought the other eteamers were, would have altered the couree eo ae to have steered at an angle away from each other. Or they could have signaled to have stopped or to have backed if neceseary, in the manner indicated on the card.

LEAD ie again in active demand in New York.

Mining in British Columbia.

According to lateet advicee from the Caribou region, mining operations of most kinds had about ceaeed there for the eeason. But little allueion ie made to the metalliferoue veine reported to have been diecovered there last year, leaving ue to infer that not much hae yet been done in that department of miuing. The bueineee eeeme, however, to be progressing fairly at one or two pointe at leaet. At last accounte tho Beedy mill on Burns' mountain was crueh-ing splendid rock, and expected a large clean-up in a few daye. The Enterprise Co.'e minee at Ieland mountain were still being worked vigorously, the ore heing hauled to the mill, a distance of two and one-third miles. The Proeperine Co. were making efforts to open their mine and develop their property. The work, however, proceeded elowly, as the company do not deeire to precipitate operatione and thereby render assessments too heavy. The Pereevcrance Co. had etarted up, and the queetion whether it is better to run a tunnel or sink on the ledge will ehortly be dctermined.

Wbile eome of the companiee engaged at placer mining in that section bave done tolerably well the past year, othere bave taken out hut little or no gold. Among the more successful companies wasbing on William'e creek the Bedrock Flume and the Black Jack are mentioned, which with one or two othere bad made large wagee, coneidering the scarcity of water towards the end of the season, much of the washing being now performed there by the hydraulic methed. Some of the companiee engaged in opening deep claime continue work througbout the winter, eome of theee claime being worked through ehafts and othere through tunnel.

The inhabitants of Caribou bave petitioned the Dominion government, praying for tbe appropriation of a eufficient eum to remove the rocks in Cottonwood canyon in the Fraser—an operation which, if eucceesful, would render that river navigable from Soda creek to the Fort George canyon, and be a great benefit to the mining section above Quesnelmouth.

THE LATEST WONDER IN ARIZONA.—The most recent novelty announced in Arizona is the discovery made at Mountain Spring Station, of either a very old and exteneive mine or a very wonderful cave, being very curioue whichever it ie. Thie opening hae a fine arcbed entrance, cut apparently out of the solid rock. At a point about 40 feet in from the mouth a room about 75 feet equare is reached, from which several halls or tunnels branch out. Seme of these have been explored for a dietance of 200 and 300 feet. There are several ehafts indicative of artificial workings. The incline of the tunnel is about 10 feet to the 100. The main cave or tunnel has been explored for about 500 feet from the entrance. The ceiling is in a red epar and in the side tunnele are numbere of beautiful etalactitee and incruetations. The direction of the excavation is toward a large ledge of mineral matter about a quarter of a mile from the entrance. Everything here eeems to point to this having been a miue rather than a natural cave. In such case it is douhly intereeting as a reminder of tho extiuct race which is known to have once iuhahited that region. A more thorougb exploration of the place is soon to be made.

THE New Almaden and the Enriquita quicksilver minee produced from January 1st, 1850 to Deccmher 31et, 1877, 650,898 flaske of metal, nearly all of it coming from tbe former. The higheet wholeeale rates at which quicksilver eold in San Francieco wae $1.50 per pound, and the loweet 40 cente, the present price.

A GENTLEMAN in Dayton, Ohio, who ten years ago became guardian of his granddaughter and took charge of the estate of $20,000 left her by her father, has juet surrendered it, increased to $40,000, upon her attaining her majority.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Arizona.

Editors Press:—Salt River valley, whence I write, and of which Phenix is the business center, constitutes, no doubt, the finest farming district in Arizona. The farmers here raise, with the help of irrigation, excellent crops, and are getting rich, as they find close at hand good markets for their produce at remunerative prices. They are therefore all right. I wish I could say as much for the generality of miners in this section of the Territory, of whom there are here a great number out of employment, and not a few hard up for the means for keeping soul and body together. The newspapers, by their constantly blowing about the great mineral wealth of this Territory, the fine openings presented for miners, etc., have caused more of people to come here than can find employment or employ themselves to advantage. The result is, we have lots of good, industrious men willing to work for their board, as many of them are now doing in this valley, where there is, of course, plenty to eat.

Another cause of hard times here has been the failure of the McCracken, the Signal, and the Golden Store mining companies up in the Hualapais district, which, after paying off their employees, and in other ways pushing into circulation nearly a million dollars of their worthless paper, closed down and left the holders in the lurch. Notwithstanding the big stories told about the yield of the mines here, the Tiptop is, I believe, the only company that pays promptly; while there are several companies here that are doing remarkably well, a much larger number are doing but little, the great majority nothing at all. There are good mines all over this Territory, but they have, at present, to be worked under so many disadvantages that it is hard to make them pay. When more mills and reduction works have been introduced into the country, and the railroad reaches the mining districts, the mines here can be worked with profit. Until then mining will be an uphill business, with some big successes and a great many failures. H. R. E.

Phenix, Arizona, Feb. 12th, 1879.

Letter from Colorado.

Leadville and Vicinity.

Editors Press:—This State is just now attracting much attention on all hands. As a bullion producer, she ranks third in the Union. The rush thither is by far the greatest seen for the past seven years, due in great measure to the wonderfully productive mines at Leadville.

Some $3,000,000 worth of gold had been washed from the creek, that passes through the town, before the silver mines were discovered. The silver deposits lie mostly between lime and porphyry, although some have a clay or gravel roof.

Mt. Bross and Mt. Lincoln Mines, in Park County.

The Con. Danville mines, on north spur of Mt. Lincoln, are producing finely, although most of the work being done here is prospecting, to prove up what they have. This property comprises about 45 acres of ground, all of which has been proven rich by drifts run in on the ore. There are at least 35 openings, nearly every one of which has exposed to view good mineral, varying in thickness from five inches to seven feet. The ore sells here from $50 to $500 per ton, averages about $140 per ton.

The actual yield of this property for the past six years, and from the average work of five men, is $141,500. A short time ago the owner, to test how much money he could take out in a short time, put five men on his best looking ore, and extracted in 70 days $23,000, receiving the money for it.

The Russian mine, corners with the Con. Danville, works from 15 to 30 men, and has produced several hundred thousand dollars. It has enough ore in sight to keep them breaking for five or six months to come.

The Gertrude has been idle for several years, but has just been reopened by lease, and a large body of gray copper ore, rich in silver, exposed, which promises to produce as in years past.

The Moose, on Mt. Bross, I am informed yielded in December more freely than for any month of the past year. This property has produced several millions of dollars in silver ore since its discovery in 1870—works over 100 men.

The Dolly Varden, same locality, has produced largely. It was in poor ore for some months last spring, but has struck it rich again, and is shipping ore regularly—works about 25 men.

Several other mines are being worked on these mountains, but those mentioned above are the largest producers. There are not less than 50 good mines on these two mountains. The present workings of these mines are in the devonian and carboniferous formations, although, it is now proven beyond a doubt that in the lower silurian formation there are fissure veins that have produced the large deposits now being worked. Oxide.

Alma, Park Co., Colorado, Feb. 3d, 1879.

Igneous Meteors.—No. 2.

[Written for the Mining and Scientific Press.]

Actual Size of Igneous Meteors.

Of course, we know nothing of the actual dimensions or masses, of such igneous meteors, as do *not* reach the surface of the earth. The meteoric stones which have fallen on the earth, vary in weight from a few ounces to several tons. The Swedish Arctic expedition of 1870, brought from Greenland several specimens of meteoric iron, the largest weighed 25 tons, and next in weight, 10 tons. There is an aerolite in the British Museum, which weighs five tons; one in the St. Petersburg Museum, weighing 1,680 pounds, which was found in Siberia in 1772; and one in the New Haven Museum, weighing 1,635 pounds, which fell in Texas in 1808. Some of the largest of such masses are composed of nearly pure *metallic iron*. One of them, the Ainsa (Tucson) meteoric iron, now at the Smithsonian Institution, weighs about 1,600 pounds; and another, the Carleton (Tucson) meteoric iron, weighs about 632 pounds, and was in the Mayor's office in San Francisco a few years ago. A mass of meteoric iron was found in 1872, near Shingle Springs, El Dorado county, California, weighing about 85 pounds.

Origin of Igneous Meteors.

The older philosophers framed various theories to explain these remarkable phenomena, which partook more or less of the progress made in the various branches of physical science. About the middle of the last century, when the effects and phenomena of electricity began to be better understood, Beccaria and Vassali, among others, regarded the shooting-stars as nothing more than electrical sparks; an hypothesis which was soon shown to be untenable. At a later period, when the inflammable nature of the gases became known, Lavoisier, Volta, Herbert, Toaldo, Gren, and others, referred these meteors to hydrogen gas, which, by reason of its small density, they supposed must be accumulated in the higher regions of the atmosphere. Dalton's discoveries exploded the physical basis of this theory. Deluc maintained that certain phosphoric exhalations generated in the earth, and becoming inflamed in the sky, formed the true essence of the shooting-stars.

With regard to aerolites, it was at one time supposed that they were also of terrestrial origin. Some imagined that they were formed in the upper strata of our atmosphere by the condensation of the vapors of solids (which were supposed to be mixed with the air), as hail-stones are formed by condensation and congelation of aqueous vapors; while others supposed them to be masses ejected from terrestrial volcanoes to an immense hight above the limits of the atmosphere, and again descending after having described several revolutions about the earth. But none of the crude theories ascribing a terrestrial origin to the various kinds of igneous meteors were able to withstand the scrutiny of exact observation and calculation, and were successively exploded by the progress of exact knowledge.

Lunar Origin.

Looking to extra-terrestrial sources for the origin of these meteors, we find that the hypothesis of the lunar origin of aerolites was originally proposed as early as 1660, by an Italian philosopher named Terzago, and reproduced by Olbers in 1795, although subsequently abandoned by the latter. This theory was sustained by the illustrious Laplace, and also by Berzelius on chemical grounds. The idea was that such masses were ejected from lunar volcanoes with sufficient velocity to pass the point of equal attraction between the earth and moon (about 24,000 miles from the center of the moon), in which case they would be brought to the earth by terrestrial gravity. It may be remarked that no improbable amount of mechanical force would be required to project a mass from the lunar surface to this point. Considering the small intensity of lunar gravity, and the absence of an atmosphere about the moon adequate to offer sensible resistance to the motion of a solid body, the force required is only that which would be sufficient to overcome the moon's feeble attraction. Calculation shows that a body projected from the lunar surface with a velocity of about 7,335 feet per second would not fall back on the surface of the moon, but would be brought under the influence of terrestrial attraction. This velocity is quite conceivable, as it is only about four times the initial speed of a cannon ball. The strongest arguments in favor of the lunar origin of aerolites are derived from the remarkable similarity of chemical constitution of the stony and ferruginous meteoric masses which have fallen on the surface of the earth; such a similarity of composition very significantly indicating a community of origin.

Objections to the Theory of Lunar Origin.

The most serious objections to the lunar origin of aerolites, as well as shooting-stars, arise from the truly planetary velocity of these igneous meteors. All the best and most trustworthy observations concur in establishing the fact that all classes of igneous meteors reach the superior portions of the earth's atmosphere with velocities frequently exceeding 20 miles per second. Now, as it is impossible for the action of terrestrial gravity to impart anything like so high a velocity to a falling mass, this physical objection seems to be overwhelmingly fatal to the theory of a lunar origin. It is desirable to place the force of this objection in a light more intelligible to the popular mind. The fundamental laws of dynamics assure us that the greatest possible velocity which a body could acquire in falling, under the influence of terrestrial attraction, from infinite distance to the surface of the earth, is about 6.9504 miles per second. The same principles also assure us that the utmost velocity which a body could acquire, in falling from the point of equal attraction between the earth and moon (about 210,000 miles above the earth's surface) to the surface of the earth, is about 6.8858 miles per second. Hence it follows that any meteoric matter which is observed to enter our atmosphere with an absolute velocity greater than about seven miles per second, could not have acquired such velocity by the action of terrestrial attraction. In order to enter our atmosphere with a velocity of 20 miles per second, calculation shows that, if such masses came from the moon they must have been projected from the lunar surface with a velocity of about 120,000 feet per second; which may be regarded as well nigh impossible.

It thus appears that those igneous meteors which have the planetary velocity of from 15 to 40 miles per second, cannot, with any probability, be regarded as having their origin in the moon. Whether any individual bodies moving with smaller velocities may have a lunar origin, is a question which cannot be satisfactorily answered in the existing state of physical science. "To me," says Olbers, "it does not appear at all probable; and I regard the moon, in its present circumstances, as an extremely peaceable neighbor, which, from its want of water and atmosphere, is no longer capable of any strong explosions."

Cosmical Origin.

The immortal Kepler imagined that there were more comets and smaller bodies flying about in space than there are fishes in the ocean. Halley, Wallis, Pringle, Maskelyne and others assigned a cosmical origin to igneous meteors, but without suspecting that masses of stone and iron fell from them. About the year 1819, Chladni announced that all classes of igneous meteors were, probably, of cosmical origin; in fact, that they were meteor-planets, of all imaginable sizes, revolving about our sun in elliptical orbits, and which, from time to time, became entangled in the atmosphere of the earth. The planetary and even cometary velocity of meteors compelled many physical philosophers, as Olbers and Arago, who at one period favored their lunar origin, to abandon the moon-theory for the more probable cosmical origin. The similarity of chemical constitution in aerolites is, after all, not so formidable an argument in support of a lunar origin; for, as Sears C. Walker justly observes, "we may as well suppose a uniformity of constituents in cosmical as in lunar substances."

Moreover, the periodical star-showers, as those of November and August, and the probable connection of igneous meteors with certain comets, point, in a significant manner, to a cosmical origin. In fact, there is now every probability in assuming that, independently of the planetary masses, there exist in the interplanetary regions myriads of small bodies which circulate about the sun, generally in groups of zones; and that some of these zones intersect the orbit of the earth, and are consequently encountered by the earth in its annual revolution.

Origin of Heat and Light.

We have seen that igneous meteors enter the upper strata of our atmosphere with velocities varying from 5 to 30 or even 40 miles per second. The enormous resistance encountered by such bodies in traversing the air, speedily extinguishes this high velocity, so that they retain but a comparatively moderate velocity on reaching the surface of the earth. In this enormous resistance and consequent loss of energy we find a satisfactory explanation of the thermic and luminous phenomena attending the fall of meteors.

The "Dynamical Theory of Heat" assures us that the energy lost by the moving body in traversing the atmosphere is transformed into heat, which is either retained by the body or is communicated to the air. The amount of heat thus generated can be estimated provided the diminution of velocity and the mass of the moving body are known. If we assume all of the heat evolved to be retained by the moving body, the increase of temperature can be computed, when the specific heat of the meteor is known: under this assumption, the increase of temperature would be independent of the mass of moving body. To apply these principles to the case of meteors traversing the atmosphere, let us assume—

Velocity on entering atmosphere.. 30 kilometers per sec.
" near earth's surface.....500 meters per second.
Specific heat of meteor.....0.22 (water = 1).

With these data, assuming all the heat generated to be retained by the moving body, calculation shows that the increase of temperature of the body would be nearly 500,000 degrees Centigrade! (For details of this calculation see *Nature*, for May 23d, 1872, p. 72.) Of course, by far the larger portion of the heat generated by the loss of energy of the moving meteor would be imparted to the air along its trajectory; but assuming that only 1-100th part of it is retained by the meteoric mass, it would be more than sufficient to account for the phenomena of fusion, detonation and brilliant light which frequently accompany the transit of such bodies through our atmosphere.

In the case of small masses it is clear that their high velocities would be more rapidly extinguished by the resistance of the air than in the case of large masses. Hence, in the small mass, the transformation of energy into heat being accomplished in a shorter time, a greater amount of the evolved heat would be retained by the moving body, than in the large mass whose velocity is more gradually checked by the resisting medium. When, therefore, the smaller masses plunge into the upper atmosphere, the matter may be volatilized by the intensity of the suddenly-evolved heat. In the minutely-divided condition in which the material of the meteor would exist after the condensation of the vapors thus formed, it would float about in the atmosphere, and ultimately reach the surface of the earth in the form of meteoric dust. The existence of such mechanically-suspended matters in our atmosphere has been revealed by the refined methods of modern research.

Thus the phenomena of the occasional fall of meteoric stones, and the almost incessant appearance of the shooting-stars which nightly furrow the celestial vault, may be correlated with the principle of transformation of energy; and all the luminous, thermic and detonating phenomena attending the fall of such bodies in our atmosphere, seem to be fully accounted for by the enormous amount of heat thus generated by their passage through the air. According to this view, the shooting stars are nothing more than small meteoric stones which are volatilized and utterly dissipated in the upper regions of the atmosphere long before reaching the surface of the earth; only the larger masses ever come down, as such, to *terra firma*.

The origin of the luminous train seems to be due to the intense heat developed on the anterior surface of the moving mass, melting this portion of the same, and the fused matter being wiped off by the resisting air, streams back, forming the train of the meteor.

Numbers of Igneous Meteors.

It has been estimated that the number of meteors that enter our atmosphere per day cannot be less than 10,000,000. "If we include those smaller meteors which are seen only in the telescope, that number may be multiplied 20 or 40 fold." Those who were fortunate enough to witness the famous star-shower of the 13th of November, 1833, can well appreciate the vastness of numbers which entered our atmosphere in the course of a single minute of time. A single glance of the eye to the celestial vault, on that occasion, revealed thousands of these meteors traversing the heavens in various quarters.

Hence it is evident that the atmosphere which envelops our planet plays an important part in shielding its denizens from the destructive effects of these extra-terrestrial projectiles. But for the action of the air in arresting and destroying these meteors, we should be intolerably bombarded with them. The absence of an atmosphere about our planetary companion, the moon, must render her liable to be fearfully pelted with these minute celestial visitors.

The Earth and Man

The earth is but to the universe as a grain of sand is to the seashore, yet insignificant as it may seem in such a comparison, it is, nevertheless, when surveyed by finite minds, a globe of no mean proportions. This mundane sphere contains 2,662 geographical cubic miles! In the mere expression of figures no particular vastness may here seem to be implied, but let us analyze the proportions of a cubic mile and our ideas will not only alter in this respect, but we will stand aghast at the magnitude of this globe, which revolves with such awful silence every 24 hours. Imagine a chest or box to have the length, width and depth of but one of these miles, and then let us see what it would contain.

To begin, cast in all the factories, public buildings, monuments, private dwellings, railways, nay, everything that has been built by man in America, add to that those of Asia, Africa and Australia, and the work is but begun. Take up the churches, towers and all other structures in London, Paris, Berlin, Hamburg, St. Petersburg, Constantinople—in short, those of every city and town in Europe. Add to that all the steamers and vessels on the ocean. What is the result? Our trunk is scarce half full!

Let us now avail ourselves of the human race. Pack them like herring in rows, and put 12,000 in a row—4,000 of these rows make one stratum of 48,000,000—just room enough for the Americans. Between each layer (to make a neat job) let us sprinkle straw and dry leaves 30 feet between each layer (which would require all there is in the world), and then pack in the 3,000,000 of Australians and 45,000,000 Asiatics, and this will complete the second stratum—and thus continue until you have the remaining 600,000,000 Asiatics, and the remainder of population, making in all 1,400,000,000 in about 30 strata. Now the chest is about half full, and it would require about 15 times the number of men to fill the remaining space. What shall we do to complete the work? Happy thought. Let us take the animals! But, oh cruel disappointment! even if we include the whole living creation, our chest will by no means be filled. And all this is but one geographical cubic mile, of which the earth contains 2,662.—*Exchange.*

MECHANICAL PROGRESS.

Room for Invention.

We frequently hear the remark that the time will soon come when the course of invention will be run; when, like Alexander, inventive genius will weep, because there are no more worlds to conquer. The fact that iron fingers have in so many branches of industry been made to perform tasks once done by bone and sinew; that electric throbbings have outstripped the fleet messenger in business affairs, and the iron horse with food of burning coals carries the love-letter and the meal-sack, where once the out-fed country steed galloped along the hard-beaten road. Those facts are impressive and suggestive, but not convincing on the subject of an ultimate limit to inventive usefulness or inventive power. The ball of progress in rolling along has wrapped about it many a layer of ideas formed into tangible facts; but the periphery grows, and the capacity for enlargement grows with it. As the circle of knowledge widens, the illimitable space beyond still more increases, and there is both more to learn and greater ability to learn it. If the *needs* of man were the sole gauge of his demands, there might well be a point at which invention, satisfied with granting all needful things, would be compelled to rest. But "to want" means both "to lack" and "to desire;" the food and shelter and clothing absolutely requisite develop into luxuries of palate and æsthetic taste. The rude needle of bone that sewed with sinew the boar-skin cloak and made of it a definite garment, was an invention that might have sufficed in its line, had the skin-garment satisfied; but demand and supply are commensurately progressive; each surpasses each, onward in the march of progress; and now we have that household companion, the sewing machine, purring like a kitten, while basting, sewing, hemming, gathering, tidily at high speed; this modern sewing machine being as legitimately the development of the bone needle, as the fashionable garment of to-day is the outgrowth of the fig leaf of Eve and the skin covering of her son.

Our wants have become artificial. With successive generations, luxuries develop into customary grants and eventually become necessities. Our condition is ameliorated, and hence our appreciation sharpened, while certain faculties have become dulled and invention must supply their places or their deficiencies. Where invention has produced an effect, it is for invention to extend and perfect it. Thus, in every walk of life it is for cunning brain and deft fingers to effect new combinations or perfect the old, fearless of thwart or limit. In proof that with improvement criticism becomes more keen, and demands more imperative, we have only to look about us for promising fields to engage the inventor. While the harvest of golden grain no longer falls before the classic sickle, and the hay maker has ceased to be a picturesque inspiration for the poet—the root-crops still demand personal delving and grubbing, and the ripened fruits still call for human pickers to pluck them one by one. For the inventors who would devise a mode removing half the blossoms from a peach tree, without injuring the buds which form the next year's bearing stems, there awaits a magnificent prize. Ramie and other fibers still defy the textile art; and the gorgeous aniline dyes fade with a summer's sun. Household fires, once synonyms of health and cheerfulness, are now gloomy and noxious monuments of our heedlessness of things sanitary. Those domestic conveniences that should minister to our comfort and well-being, poison us insidiously but surely. Our vaunted gaslights blacken our paint and kill our window plants, while in the street, the pipes which lead the gas destroy our shade trees. Our sewers and our drains are confounded in name and in use, and both of them are poisonous. Our chimneys breathe forth smoke which is unconsumed fuel, and hence wasteful. Our steam-boilers, with partly consumed fuel, supply our engines with wet steam, and the engines (whose cylinders have to be supplied with oil, through faulty design and workmanship) waste part of the remainder. Our horses, shod with no regard to humanity or for tractive effect, draw wagons or cars which rattle our teeth out, on roads or rails which rattle the vehicle to pieces. The explosives which long ago were constrained to throw hurtful missiles, have but in one instance—blasting—been employed in peaceful work; if we may except the gunpowder pile driver, the precursor of a long line of explosive motors yet to come.

For these and hundreds of other evils, inventive genius must provide the remedy; and as new and artificial wants arise and develop into necessities, upon the inventor, ever in the vanguard, devolves the duty of exploring the land of the possible and providing for the legions of the actual.

It might be said that as science falls into the ranks of knowledge, and art after art is added to the forces of man, the field of true invention would narrow, and that of improvement, combination and application correspondingly widen. And this distinction may not perhaps be improper to draw, nor inappropriate to apply. Certain it is, that as observation and experience lay down the facts, and reason deduces therefrom the theories and evolves from these again the laws which govern things tangible and forces intangible, the plane of the inventer will rise higher and higher, and his usefulness will never diminish. It is to him that races unborn, nations unformed, countries unexplored, look to for their betterment and the achievement of their substantial welfare. Through him the antagonism between man and man—the foul distinctions of caste and class—will be swept away; and better men, under better lives and higher pleasures and comforts, achieve the destiny written for them in the days when the rocky ribs of this earth were formed.—*Polytechnic Review.*

A Planing Machine for Granite.

The Boston *Advertiser* for January 2d, contains, under the head of "Granite Planed Like Wood," an article on a new machine for planing stone rapidly, built on the principle of the wood-planing machine. The article begins by saying that when swiftly revolving knives were first made to do the work of horizontal planes upon plank and board, great wonder was expressed, and the planing machine came at once to be the talk of town and country. We have all become used to that and see no impracticability in the use of steel vs. wood in the rapid displacement of the rough surface of the latter.

Next in order one might reasonably expect that some ingenious man would devise a method for the cutting of soft stone, such as freestone, sandstone, and the like, but that chisels or tools of any sort that could be made, would, when driven, dull quickly, and render the operation practically of little value. Such a plan for the cutting of marble could not be entertained, for the hard material must be removed by well directed strokes from a powerful arm. The inventor of the above mentioned machine has now shown what may be accomplished. Disdaining, as it were, to meddle with softer substances, he selects for the test of his invention the hardest of all—granite, and the hardest granite at that—Hollowell. Easily and simply as the surface is removed from a pine board and caused to fly off in chips, the flinty roughness is made to leave the face of the great block, and only a fine powder remains to prove that a strange work has been done by the ingenious application of steel. "If there could be made a tool that would not require constant watching and very frequent sharpening, you might plane granite," said a practical granite cutter. The inventor showed him that for 45 minutes his machine could run continuously and the tools be uninjured, and he was not a little surprised to note the amount of work done by the machine in that short space of time. The tools can be changed in a few minutes, and the whole machine at once put into operation.

COMPRESSION BY STEAM IN CASTING.—In some recent French experiments it was noticed that when a lid of cast iron was placed upon a mold after casting, the ingot produced generally showed a zone of blow-holes near the surface and on all sides, while within it the block was entirely sound. Whenever the mold was not covered the entire mass contained blow-holes. This, it was urged, was due to the pressure of the gases, and consequently experiments were made by Bouniard with more than 100 tons of steel, which proved that a pressure of 6 to 10 atmospheres acting upon the interior of the ingot would make the metal solid. The mold is covered with a lid in which there is a central casting opening. It has a pipe through which steam may be introduced. The steel is cast through the central orifice, which is closed, and then steam is admitted. A copper wire is used for packing the lid. The work must be rapidly done and the mold be previously heated. In order to make the action of the pressure affect the interior of the ingot the chilling of the surface must be prevented, which is done by heating, before casting, the fire-brick lining of the inner surface of the lid. The ingot thus cast shows a depression on its upper surface. It was found that in using steel for cannons the number of compressed ingots rejected was only one-third of the number of ordinary cast ingots. Experiments made to apply the same principle to steel castings showed that although the application was more difficult, the result was the same.

A NEW system of exhaust valves for steam engines has recently been introduced in Germany, which has been pronounced by *Dingler's Poly. Journal* to embody an idea which may prove of great consequence. The admission valves alone are actuated from without by flat slide valves, moved by geared segments, while the exhaust is effected by two valves placed at the two cylinder covers, which are so connected with a double-armed lever placed in the exhaust passage, that when the one valve is closed the other is opened. If, therefore, one exhaust valve is closed by the steam pressure, the other is opened to the exhaust steam, until the steam enters on the other side of the piston, which causes the latter valve to close immediately, while the other is opened full.

GREAT efficiency in steam engines is, according to Mr. Walt, an eminent Liverpool engineer, to be obtained by an increase of pressure and expansion. To accomplish this the point lies not so much with the engine as with the boiler, engineers finding no difficulty in working an engine with steam at 150 or 200 pounds per square inch; and at present he thinks there is no practical limit to the working pressure. Some engineers will be inclined to differ with this opinion, for the management of steam used expansively in simple reciprocating engines at ranges of pressure much exceeding those named, to secure the theoretical economy due to full expansion, would certainly be attended with difficulties.

SCIENTIFIC PROGRESS.

Instantaneous Photography.

The remarkable success attained by Mr. Edward J. Muybridge, of this city, in the production of accurate pictures of horses in rapid motion, has stimulated other persons in a similar direction. The process has recently been applied by Gen. Abbott, of the United States Engineering Corps, for recording the effects of the most sudden and violent explosions by gunpowder and dynamite. The General has shown that however instantaneous an explosion appears to take place, it occupies, notwithstanding, a measurable amount of time, which can be readily measured and the accompanying effects accurately recorded by this new application of the camera.

Among other experiments, Gen. Abbott employed that instrument to make a series of pictures of the different stages of the explosions of submarine torpedoes. In order to accomplish this, according to the *Manufacturer and Builder*, and in order to make six pictures, he had a key-board constructed like that of a piano, consisting of seven keys. The pressure of each of the keys closed a circuit; that of the first key went to the torpedo and exploded it; the remaining six keys were each connected with a fuse, which sustained by a thread the screens of six cameras, prepared to take pictures of the explosion. Any of these keys, when touched, ignited the fuse, which disrupted the thread and dropped the screen; in the latter was a hole, passing before the objective of the camera, giving, during that passage, an exposure of which the time was estimated to be at most the one-twentieth of a second. If, now, the keys of this key-board were rapidly played, all the seven keys could be touched in succession, in any previously determined velocity, always giving first the explosion itself, and then the exposure of its effects in the cameras in successive periods of tenths of seconds, or more or less, as desired.

The first experiment was with the explosion of 500 pounds of dynamite, estimated equal to 5,000 pounds of gunpowder, and the pictures taken at intervals of one-tenth of a second, so that all the successive pictures were taken in not much more than half a second. This is not even a very rapid succession, as almost any pianist can easily play twice as many successive keys in that time. The result was an explosion in the pictures of all the successive results, analyzed and in order. Among other curious effects, the photographs showed that a plane horizontal force was developed by the explosion.

Other experiments showed that depth was an important factor. The torpedoes were exploded near together, one three and the other six feet deep; the first threw up a column of water twice as high as the latter. To ascertain how a torpedo affected a hull, or broke up a ship, two charges of 50 pounds each were placed three feet under the bottom of a hull. The eye saw nothing but a confused outburst of water, by reason of the persistence of images on the retina; but the photographic camera was very much quicker than the eye, as proved by the series of photographs, which showed the whole manner in which the hull yielded to the shock, the shape and position of the different fragments while flying up in the air and coming down again. All this was distinctly pictured in the series of photographs; still, from the time the torpedo was fired until the pieces had come down, only about two seconds elapsed, while in four and one-half seconds the water where the vessel floated was quiet again.

THE SIZE AND FIGURE OF THE EARTH.—Prof. Listing gives in the *Astronomische Nachrichten* the following results of his determination of the constants of the earth's figure: Equatorial radius, 6,377,377 meters; polar radius, 6,355,270 meters; mean radius, 6,377,000 meters; equatorial quadrant, 10,017,560 meters; meridian quadrant, 10,000,205 meters; eccentricity of meridian section, 288,480; length of second's pendulum at equator, 45°, and pole, 990.9948, 993.5721 and 996.1495 millimeters, respectively; force of gravity at equator, 45°, and pole, 9.780728, 9.806165 and 9.831603 meters, respectively; also in general the length of the second's pendulum equals (in millimeters) 990.9948 plus 5.1547 times the square of the sine of the latitude; and the force of gravity equals (in meters) 9.780728 plus 0.050875 times the square of the sine of the latitude.

NEW ELECTROTYPE PROCESS.—A new and ingenious process has lately been introduced into France, for electrotyping on non-conducting materials, such as china, porcelain, etc. Sulphur is dissolved in oil of lavender spike to a sirupy consistence; then chloride of gold or chloride of platinum is dissolved in sulphuric ether, and the two solutions mixed under a gentle heat. The compound is next evaporated until of the thickness of ordinary paint, in which condition it is applied with a brush to such portions of the china, glass or other fabric as it is desired to cover, according to the design or pattern, with the electro-metallic deposit. The objects are baked in the usual way before they are immersed in the bath.

Spontaneous Combustion by Zinc.

Dr. Hoffman has called attention to some curious cases of spontaneous ignition of hydrogen in air. The phenomenon has been noticed in factories where quantities of zinc were being dissolved in hydrochloride acid for the preparation of zinc chloride. Violent explosions took place when no flame was near; and it was eventually ascertained that the gas took fire spontaneously. It appears to be caused by fragments of very porous zinc, which, when lifted above the surface of the liquid during the violent evolution of the gas, and so brought in contact with hydrogen and air, act just as spongy platinum would do under the circumstances. The author recommends the performance of such operations in the open air. The ignition can be shown by treating a few kilogrammes of finely divided zinc with acid. The "zinc dust" may even ignite by contact with water.

A recent issue of the *Insurance Record* calls attention to the dangerous character of zinc dust, which appears to be imported into this country in considerable quantities for use in certain branches of industry.

The material presents the appearance of a gray powder, in an extremely fine state of division, in which condition it is largely used in the manufacture of paints. Chemically, it contains as much as 40% of metallic zinc dust, the remainder being oxide and carbonate. Another variety of the same commodity, known commercially as slate-colored zinc oxide, contains really very little or no oxide at all, being almost wholly a metallic dust, which, in the process of manufacturing zinc-white, has escaped combustion, and is deposited in the flues of the condensing apparatus. These products, the *Insurance Record* points out, are extremely apt to originate mysterious fires, if precautions are not taken to keep them from contact with moisture; for, owing to its very fine state of division, this metallic dust, in the presence of water moisture, will eagerly oxidize, and as this oxidation will be attended with a very considerable rise in temperature, the hydrogen gas evolved in the process may be inflamed, and, directly or indirectly, inflammable materials in the neighborhood may be ignited, and in this way the building or ship in which it happens to be stored may be destroyed, while the cause of the disaster may never be suspected. The *Record* points its moral by citing the case of the fire in the steamship *Lord Clyde*, in the year 1876, and which at the time attracted some attention. The facts in this case were about as follows: A number of casks of zinc dust were placed in the hold of the vessel, without any notice of the dangerous character of the material having been given to the owners of the ship. The casks, or some of them, by some means got wet, and within 12 hours after they had been put on board, the vessel was found to be on fire. When the source of the fire was discovered, the contents of one of the casks were found to be red-hot. As another contribution to the causation of what, for want of a better term, are called "spontaneous" fires, the facts above detailed are worthy of special attention.

Solidified Hydrogen or Hydrium.

The success which has been obtained in liquefying the gases thus far supposed to be permanent, it appears certain that not only liquefaction but also solidification has been achieved.

Pictet, in a very recent experiment with hydrogen compressed at 650 atmospheres, found, on opening the stop-cock, that the gas issued with a noise like that of a hot iron bar under water, and it had a steel-blue color. The jet suddenly became intermittent, and then there followed a sort of hail of the solid particles of hydrogen, which fell with violence on the ground and produced a crackling noise. Afterward the stop-cock was closed, and there was evidence that a crystallization of hydrogen took place within the tube; but when the temperature was again raised, the gas issued as a liquid.

M. Dumas, the President of the French Academy of Sciences, accepts these facts as full of confirmation of the theory, long ago advanced, that hydrogen is a gaseous metal. As water is an oxide of hydrogen, it follows from this that when a person drinks a glass of water, he imbibes a metallic oxide. *Nature*, in mentioning these performances, coupled with them another, which it regards as yet more remarkable from a scientific point of view. M. Pictet has been able to measure, with a very close approach to accuracy, the volume occupied by a given weight of oxygen in the liquid state; this was found to agree with the volume calculated for the solid or liquid gas, on theoretic considerations, by M. Dumas. By means of two Nicol prisms, M. Pictet observed the jet of liquid oxygen in polarized light, and found strong evidence of the presence of solid particles.

As in the chemical nomenclature the final ending "um" has been adopted for all metals, it is proper to call this metallic hydrogen, "Hydrium," a name which has already been used by the latest authors of German text-books of chemistry, even before hydrogen had been liquefied or solidified.

BEHM & WAGNER'S tables have lately been published, and show a total increase in the population of the earth of 15,000,000, partly arising from natural growth and partly from the showings of new and more exact censuses.

Mining Share Market.

We have had a dull and uninteresting week in stocks. With one or two exceptions, the market has been entirely destitute of animation. The transactions on the Boards show how suspicious small dealers are, that the various deals have reached their culminating point. They touch tenderly, letting go on the first appearance of weakness. Shares are too well concentrated for insiders to dispose of them immediately. The only thing to be relied on for a general redistribution, is the probable development of an ore body. What movements have been perceptible, have been discouragingly sluggish, the animation resulting rather from the policy of inside manipulators, than an outside demand for shares. The principal deal has been in Unioa Con., which rose about $30 at the middle of the week, only to fall again, toward the latter part, to nearly its old level. Why the spurt took place is somewhat of a mystery. There were no developments to warrant the jump, and we can only explain it on the theory that it was a test of the "gambling" feelings of the community, to see how far they would respond to an opening of the market. Evidently, the response was not wholly satisfactory. Reaction was almost immediate, and stocks took an inexplicable fall, as sudden as their rise. The break not only wiped out all the appreciation, but, through sympathy, brought down seriously many stocks which had not participated in the rise. The bonanza shares were principally affected. Toward the close of the week, efforts were made to arrest and liven the market, and the old rule was put in practice, of selecting and supporting one particular favorite, as a prop to the others, and thereby to restore the wavering confidence of the people. Mexican was the one selected, and some little excitement was raised. Most stocks rallied. There was a slight rise in the Tuscarora. Summit advanced sharply, while Bodie and Raymond & Ely slightly declined. No other important changes in ontside stocks. The Comstock remained steady, but with orders limited. The market generally closing steadily.

Irrigation in Nevada.

The Wiuaemucca *Silver State* of Jan. 22nd, says that the "Humboldt Irrigation and Development Company" has been formed, composed of Sacramento business men, for the purpose of diverting the Humboldt river for irrigatiou and agricultural purposes, and to bring the barren wastes into market. To this end, a dam at Oreana, 12 miles from Lovelock's, has been constructed at a cost of $15,000. This brings the water to within one foot of the top of the soil at the head of our valley. The construction of the ditch or canal, with sufficient capacity to divert nearly all the waters of the Humboldt, is being rapidly pushed at this time, and when completed will be nearly 20 miles long. Also a smaller ditch meandering under the foothills, which, when it reaches opposite Lovelock station, will afford as fine a waterfall as can be found in the State—a fall of 40 feet—which will afford ample water for flouring and quartz mills, and not detract from the main object—that of irrigation. This ditch and dam, when completed, will cost in the neighborhood of $100,000, and will give us a front rank as an agricultural community. We are also on the great highway of natioas—the Central Pacific railroad, which spans the whole valley, and with proper facilities for freight, we can at all times ship aay and all surplus we have on hand; also, affording abundance of feed for fattening stock for the California market.

New Incorporations.

Diamond Creek G. & S. M. Co.—Diamond Mountain District, Nevada. Capital, $5,000,000. Directors—Albert C. Shaw, J. C. Cable, Jacob Weissbein, William Word and Joha Warner.

Representative G. & S. M. Co.—Capital stock, $10,000,000. Directors—E. J. Baldwin, J. P. Cavallier, Alex McAbee, R. E. Kelly and J. J. Maue.

De Ruyter G. M. Co.—California. Capital stock, $500,000. Directors—T. A. Talbert, Thos. W. Cuaningham, John Day, J. W. Roherts and A. D. Rightmire.

The Cozian, the Witch, and the Haley and Militich G. & S. M. Co.—Baranoff Islands, Alaska. Each has a capital of $1,000,000, and the Trustees of each are as follows: S. B. Watson, Walter Hoge, Robert Kanzie, E. Chielovich and L. Radovich.

Pacific Coast Oil Co.—To deal in oils and oil lands. Capital stock, $1,000,000. Directors—Charles N. Felton, L. D. Fisk, George Loomis, George W. Heges and E. H. Forester.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Tybo Con., Feh. 17th, $4,089.90; Ophir, Feh. 22d, $79,230.38; Hillside, Feb. 24th, $5,470.00; Independence, Feh. 24th, $6,000.00; Grand Prize, Feb. 24th, $14,500.00; Paradise Valley, Feb. 21st, $29,300.00; Christy, Feb. 24th, $5,902.00; Tyho Con., Feh. 19th, $4,274.77; Northern Belle, Feh. 22d, $9,136.74; Paradiso Valley, Feh. 24th, $3,400.00; Highhridge, Feb. 25th, $4,250.00; Martin White, Feb. 23d, $6,960.00; Hillside, Feb. 26th, $5,530.00.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Phœnix. *Dispatch*, Feb. 22: The deepest point reached is 1,250 feet, and the lowest level at 1,200 feet; both developing finely. Nearly the whole of the ore now taken out comes from between the 1000 and 1100 levels. There is plenty of water in the ditch for all purposes. Besides timbers, from 20 to 30 cords of wood are floated through the ditch daily. Eight cords per day are consumed by the furnace, the surplus being stored for summer use, to tide the works over that portion of the year when wood-floating is impractical. At the head a boom has been constructed across the middle fork of the river, not for the purpose of stopping the logs entirely, but to guide them into the ditch. Besides supplying water for their own works, the company run 600 inches to Michigan bar, $75 to Irish hill, and 200 to Forest Home.

Amador Con.—The sluking of a new shaft has been commenced on the old Wolverine ground, which has not yet been explored to any extent. A strong force of men are employed in sinking operations and in tearing down the buildings over the Eureka shaft, which are to be erected over the mouth of the new opening. This move is looked upon as insuring the working of the mine for many years.

The Centennial.—This mine and mill are under attachment from several parties. The ore looks splendid, but does not contain much gold. Repeated assessments have discouraged many of the stockholders, or exhausted their purses, consequently the last assessment is unpaid to a great extent. Between 2,000 and 3,000 shares were bought in by the company. Still, work is proceeding in the mine. Miners are running a drift west, in the hope of striking a richer body of ore, which, from surface croppings, is believed to exist in that direction. The mill has been shut down for some time.

Notes.—At Ophta, S. H. Clarke has a five-stamp mill operating on goldta, by using cement. The cement cannot be worked by hydraulic power. It has to be blasted from the mine, and is put through the mill like quartz, the five stamps crushing some 40 tons per day. A clean-up was made the other day, with highly satisfactory results. The Pennsylvania, at New Chicago, is still idle, and no immediate prospect of resumption of work. The miners who were engaged by the company at the time of the cave have tired of waiting for it to start up, and scattered in search of employment elsewhere. The English company owning the Original Amador have purchased the Maryland mine for $12,000. This property adjoins the Seaton, lately purchased by the same company. Few men are at work at present, but as soon as spring fairly opens a strong force will be put on. A crushing of rock from the St. Louis mine, on Kennedy flat, is to be made soon at the Oneida mill.

CALAVERAS.

Gwin Mine.—*Chronicle*, Feb. 22: Considerable trouble has been experienced by the breaking of pump-rods There is a good deal of water in the mine, and notwithstanding the pumps have been increased in size they have to be run beyond a safe rate of speed to keep it down. Aside from that everything is progressing favorably, the batteries being at present supplied from the 1400 level.

Struck It.—An enormously rich quartz vein has been discovered near the North Fork of the Mokelumne, in the West Point district, by a gentleman from Mexico. We have no particulars of this find beyond the announcement that the ledge is wide and the rock very rich.

Upper Country Mines.—The shaft of the Champion is now down 500 feet and a station is being put in at that depth. Drifting to strike and crosscut the ledge is also commenced. Some parties have commenced taking ore from the San Bruno at Mosquito. Operations at the San Pedro, Glencoe district, continue to be conducted with great zeal, and rapid progress is being made in sinking the new shaft. At the Banner, same district, everything is running smoothly, the work of extracting rich ore going steadily on.

INYO.

Benton.—Inyo *Independent*, Feb. 15: The Comanche company have resumed operations again. Our letter, under date of 12th instant, says: "The mill started on tailings on the 5th, and is working at a good profit; will ship a number of bars next week. The hoisting works of the Kerrick mine have been removed to the Tower, the entire change being accomplished and the machinery set in motion again in five working days, exclusive of two days on the teams.

Struck It.—The old Fish Springs gold ledges, some 18 miles north of town, have been re-opened and prospected by the lessees, Olmstead & Davis. They have been successful in finding the lost ledge in the old workings, with plenty of ore running from $75 to $150 per ton in gold. Mr. Westerville is setting about to repair the old arastras.

Running.—The Brown Monster mill has been running 30 stamps steadily for some time, and partial clean-ups so far indicate complete success.

MONO.

Standard.—Bodie *Standard*, Feb. 22: The east crosscut from the main shaft is in 273 feet; progress for the week, 28 feet. The rock in the face is in porphyry, with stringers of quartz. The south drift from this crosscut has been advanced 18 feet, total length, 207 feet. The ledge is three feet wide, of very good ore. The east crosscut, 300 level, old shaft, is in 225 feet; progress for the week, 10 feet. No change in the character of the ground. The north drift from the crosscut has been extended during the week 14 feet; total length, 66 feet. The ledge is two and one-half feet wide, and looks well. The north drift on the West Standard is in 70 feet. The ledge is 18 inches wide, of very rich ore. The south drift on this ledge is in 69 feet, showing a ledge two feet wide, which is also very rich. The north drift on the Cook ledge is in 130 feet. The ledge is 18 inches wide, and looks well. The tramway has not been running for two or three days. The cable is worn out, and a new one is expected from Pillston, Pa. Two cables have now been worn out. The first lasted eight months, and the last but three months. The new one will be a three-quarter-inch steel wire affair, while its predecessor was but five-eighths. For the present the ore is being hauled by teams.

Red Cloud Con.—The west crosscut, 400 level, is now in 50 feet. The rock in the face is becoming harder. A progress of a few feet has been made in the east crosscut, same level, without material change. On the 250 level fair progress has been made on the west crosscut from the north drift. A winze has been started on the Packard and Morton vein, which is now down 10 feet. The mine has been cleared of water since the strike, and everything is working well.

Belcher.—The south drift, 380 level, is in from the winze 165 feet; progress during tho week, 10 feet. The ledge is two and one-half feet wide, and looks well. The west crosscut from this drift is seven feet. The rock is very hard. The ledge in the upraise is two feet wide, of good ore. The ledge in the south drift, 200 level, is three feet wide, and looks well. No important change in the Stonewall stopes, which are yielding the usual amount of good ore.

Maryland Con.—Work is going on with more than usual activity. The ledge is keeping its usual width, with an increase of quartz, both in quality and quantity.

Queen Bee.—The mine has resumed work after the strike, with the usual number of miners. Drifting has commenced north, and a fine lot of ore being taken out, which is saved for milling. The east crosscut, 250 level, is being continued, and is now in 38 feet. The west crosscut has been discontinued for the present and the force placed at work on the ledge.

Mono.—Work has not been discontinued in this mine during the strike. The north drift, 400 level, is in 45 feet from the shaft. The ground works well. The west crosscut from the north drift, at a point 18 feet from the shaft, is in 25 feet. It has passed through some hard rock and streaks of mineral-bearing quartz.

University.—Since last report the 100 level has attained a total length of 184 feet; 15 feet progress during the week The crosscut from the bottom of the shaft is in 22 feet, cutting through nine feet of ledge matter, four feet of which is quartz; prospecting well.

Harrington.—The tunnel has been advanced 15 feet during the past week On the 12th inst. a ledge was cut consisting of a heavy character of clay and two feet of quartz. Being near the surface it is considerably broken. The hanging walf has not been reached yet, as in driving ahead alternative veins of quartz and porphyry are cut.

Goodshaw.—The east crosscut, 450 level, was advanced nine feet during the week, and the west crosscut six feet. Work was suspended during the strike, which fact has caused a less progress than usual. The full complement of men is now being worked in the bottom, and everything is running as formerly.

South Bodie.—Work was resumed this morning Sinking will be continued with all possible speed until the depth of 500 feet is reached. When ordered to quit work in the shaft by the Mechanics' Union, several small veins of quartz were running in the bottom, assaying $21.

Summit.—The station at the depth of 200 feet has not yet been completed, and the skip runs are not yet in, owing to the delay of several days during the week, occasioned by the strike. Sinking and drifting will be commenced as soon as this work is completed.

NEVADA.

Hydraulic Mines.—*Union*, Feb. 25: Mr. Thomas, on the "Slide," has secured from the V flume, a good head of water, and is running with 400 inches, using one giant, and piping until ten o'clock at night; in a few days will commence running night and day as long as there is sufficient water. The bank is about 60 feet in hight, composed of soil, pipe clay, containing seams of gravel, and a fine blue gravel layer next to the bed rock. The bed-rock is generally a soft blue slate, which picks easily, and slackens by expose to the atmosphere. When this bed-rock is washed clean of gravel the fine gold can be seen sprinkled over it quite liberally. Mr. Thomas holds a large piece of this ground to the north of town, secured by U. S. patent, and has lately increased its area by the purchase of the ground that belonged to the Dartmouth company.

Watt Gravel Mine.—This has been drifted 26 feet in the east drift this week; there is not any change in the appearance of the drift since last report; everything is running as usual.

Alaska Mine.—The hoisting works over the new shaft are completed, and the raising of ore commenced. No. 1 level is opened several hundred feet, and from this part of the mine the best paying rock has always been taken. The Alaska-Bullion combination shaft is down 55 feet below the No. 3 level, and showing a strong ledge all the way. A new contract has been let to sink the shaft 30 feet deeper, and upon the completion of this contract a new level will be turned. The No. 3 level is in a good quality of milling ore, and is producing sufficient to keep eight stamps going. The ground on this level works easily, and rapid progress is made in extending the drifts.

The Pittsburg Mine.—*Transcript*, Feb. 29: The mine presents favorably. The ledge in the 600 north drift is well defined, carrying a large amount of sulphurets, and free gold being visible. The ore in the 700 north stopes is looking well. The 800 north stopes are yielding good ore. The ledge in the 800 south stopes is also doing and yielding fairly. Owing to the late storms the water in the mine has very materially increased. The pumps are doing fairly and will, no doubt, be able to keep the mine free from water.

PLACER.

Dutch Flat Hydraulic Mines.—*Herald*, Feb. 22: The hydraulic claims at Dutch Flat have commenced running for the season. The Polar Star and Southern Cross are in full operation. The water is taken from the South Yuba ditch. Between 40 and 50 men are employed. The wages are $35 per month and board, or $2.10 per day without board. A new Superintendent has taken the place of Mr. P. Colgrove. Mr. Samuel Colgrove. Mr. Samuel Harriman is the sub-Superintendent. Mr. Robert Simmons is the foreman of the Polar Star, and Mr. Charles Hilton, of the Southern Cross. The Frauklin, now owned by a company of capitalists of San Francisco, has also commenced work under the management of Mr. James Taaffe. This claim also uses water from the South Yuba ditch. Mr. Lecamp's claim has also commenced running. Some half a dozen men are employed. The wages of the men are $3 per day without board. The Central has also started up for the present mining season. The other claims of the Cedar Creek company are not working, on account of law matters, not yet adjudicated. The Jehosaphat claim is worked out, but the Baker claim paid well during the last mining season. There is a rumor afloat that the Englisb Co. have sold out.

SHASTA.

Copper City.—Reading *Independent*, Feb. 24: Everything is all right with the Extra company, which was reported failed. The present indebtedness will be paid in full, and instead of checks, cash will be paid hereafter. Mr. Crane has everything in good shape to produce bullion. The mill is in good running order, the tramway is completed, and a rich vein of ore has been discovered, and the creditors will all help him out. The mill will still be run, and that on a cash basis, and bullion will continue to be produced in even greater quantity than heretofore. That the mine is rich, there can be no doubt, as the shipment of over $100,000 in bullion within a period of six months will testify, and if the bullion is there, this temporary suspension cannot affect it.

Items.—A quartz mill is at the depot for the Mad Ox mine, near Whiskytown, owned by Messrs. Hull, Biekford, Orotefend and Stroud. Thus the Afterthought mill will be ready for business about the 1st of April.

SIERRA.

Savage Placer.—Downieville *Messenger*, Feb. 22: Work is going ahead on the tunnel of the Savage Placer Co. There is now two feet of snow at Downieville and it is much deeper at the mine. Supt. Mooney telegraphs that he has not heard from the mine for eight days. He made several attempts to go to it but was unable to get through. He has sent a man up on snow shoes. All is no doubt going on as usual at the tunnel, as the men have an abundanee of provisions and supplies of all kinds and are well and comfortably housed. At the works there are buildings with a long shed leading to the dump from the mouth of the tunnel.

NEVADA.

WASHOE DISTRICT.

Sierra Nevada.—Gold Hill *News*, Feb. 20: The work of sinking the incline is making all the progress possible with present facilities. It is 38 feet below the 2300 level. The face continues in cap rock. The north drift, 2200 level, is still in soft, treacherous ground which needs to be well timbered. The heat also interferes with rapid progress. The face is, however, 300 feet from the north crosscut, and in good working ground. The east shaft will reach the 2200 level this week. A sump will then be sunk and after that a drift will be started south to meet the one going north. Good progress is being made in pushing the upraise from the 1700 level up to meet the shaft of the North Con. Virginia.

Gould & Curry.—Crosscut No. 1 east, 1900 level, on the Best & Belcher line, has been started and is in 25 feet in hard porphyry. Crosscut No. 3 east, same level, has passed through a mixture of hard clay and porphyry, and is now in hard porphyry. Crosscut No. 4 west is in vein matter consisting of quartz and porphyry. No work is being done in Nos. 2 and 4 crosscuts east.

Utah.—The new hoisting engines are now ready for use, but the cable for the incline has not yet arrived. The incline has been carried down in good ground 328 feet below the 1350 level.

Lady Bryan.—The shaft is being continued on down through bird's-eye porphyry and quartz; the drifts north and south on the 600 level are also in vein material giving low assays, and the west drift on the 380 level is in quartz and porphyry.

Best & Belcher.—West crosscut No. 3, 1900 level, has penetrated a lively looking vein formation 111 feet, and continues in the same material.

Ophir.—Everything going on again as usual. The break of last Wednesday has been repaired and sinking resumed in the main incline, which continues to penetrate porphyry.

Mexican.—The joint Union Con. winze from the 1600 level is being sunk and timbered at the rate of three feet per day, and is now 253 feet, on the slope, below the level. The material continues to be hard blasting porphyry.

Justice.—The drift from the Alta to connect with the bottom of the winze below the 1300 level is making good headway through a kindly formation of vein matter containing narrow veins of rich ore.

Leviathan.—The repairs to the main shaft are completed and work going ahead lively in the lateral drifts, both north and south, on the 750 level.

California.—The upper levels of the mine are yielding their usual amount of ore, and show no changes worthy of note.

Chollar-Combination Shaft.—Fair progress is being made in sinking, notwithstanding the abundant flow of water, which is slightly on the increase, coming in from the southwest corner. This is hoisted to the surface by the skeets. The water raised by the pumps is all discharged into the Sutro tunnel.

Savage.—Last Thursday all prospecting work was stopped in the mine. The last work done was in the south lateral drift on the 2100 level and from the winze. This had reached at that time a distance of 313 feet. The pumps are holding the water 40 feet below the 2000 level.

Belcher.—Sinking the main incline, which was resumed last Thursday, is making excellent progress, the face being 75 feet below the 2560 station. The south drifts on the 2560 and 2300 levels are also being rapidly pushed forward through good working ground.

Silver Hill.—The main incline continues to encounter hard black rock, making progress slow. The east crosscut, 1100 level, is making rapid headway in a dry formation of porphyry and clay.

Julia Con.—The pumps are running well and the balling tanks are also in use. These appliances together are holding the water down. Preparations to turn this water into the Sutro tunnel will be completed Thursday night and the whole of it will be raised to the 1600 by a Cameron pump and discharged through the connection as soon as word is received from Mr. Sutro authorizing it, in accordance with the contract.

Con. Virginia.—The joint Best & Belcher crosscut west, on the 1950 level, and joint winze, are receiving the usual attention, the former being in quartz and porphyry and the latter in hard porphyry. The C. & C. shaft is being pushed on down as rapidly as the hardness of the rock and the large amount of water will permit.

Ward.—The new machinery will be ready for operation by the 15th of next month. The east crosscut, 800 level, is in 458 feet, the face in bird's-eye porphyry with stringers of quartz. This is being pushed to prospect the vein underlying the croppings to the east, which it is expected to reach when in 800 feet.

North Con. Virginia.—The large water tank below the 1600 level is in place and all completed except calking. It is 18 feet long and 9x8 in the clear. The large and convenient blacksmith shop to the east of the works is finished and in use.

Overman.—The work of sinking the O. & C. shaft is suspended to-day to put in the new steel skeet, but will be resumed again this evening and will thereafter make five feet per day.

Bullion.—The Combination Bullion-Exchequer drift on the 2400 level is cutting soft vein porphyry containing stringers of quartz and making good progress.

Hale & Norcross.—Very little is being done in the mine except pumping. The water is held 32 feet below 2000 level. The winze from the east drift on this level is down 44 feet.

Con. Imperial.—A survey is being made for the purpose of running a drift south from the station on the 2600 level of the old workings of the Yellow Jacket.

Alta.—The principal work on hand at the present time is that of placing the new double engine at the head of the joint Alta-Benton winze from the 1550 level.

Union Con.—The north drift, 1450 level, connecting with Sierra Nevada, is still being repaired. From the 1600 level the joint Mexican winze is averaging three feet per day, and is now 253 feet in depth, the bottom still in hard blasting porphyry. The flow of water from the east drift continues to decrease.

Yellow Jacket.—The new shaft has been sunk 10 feet below the 2280 level, and a pump station is being chambered out. When this thing is completed sinking will be resumed. Surveys are being made for connections between the 2600 level of the Imperial and the 2400 level of the old works.

Crown Point.—The usual repairs to the incline, etc., are going on. The drift north on the 2500 level and from the bottom of the winze is still skirting the vein and cutting a kindly formation of soft rock which admits of excellent progress. The drift is now in 112 feet.

Solid Silver.—The retimbering of the main tunnel in the caved ground at the north end is steadily progressing, and it is being enlarged for a side track in order to take out ore when the main ore chimney shall be reached and re-opened.

Caledonia.—Drifting east on the 1600 level in hard vein porphyry and making good progress. The vertical winze to the 1900 level is in a soft, friable formation of vein porphyry and is being sunk with all possible dispatch.

Succor.—Sinking the shaft and drifting both north and south on the 1050 level. The formation encountered in both these drifts continues promising.

New York.—Sinking the incline below the 1040 level, as usual, and making good progress.

EUREKA DISTRICT.

The Hamburg.—*Sentinel*, Feb. 25: Mining operations for the past week have progressed as usual. An upraise of 23 feet at the north end of Intermediate drift below 250 level has been made. The 400 level, west crosscut, advanced 15 feet, making a total of 135 feet from the south drift. South drift from west crosscut advanced 15 feet, making a total length of 71 feet; face in favorable vein matter, showing some buches of good ore. The winze was sunk 13 feet, making a total depth below the 600 level of 50 feet, with a considerable showing of iron in the bottom.

Charter Tunnel.—The suspension of this company is but temporary, and they are preparing for active operations. Three specimens of ore from the Tunnel were assayed by Walter Brooks during the week, yielding, respectively, $4.70, $15.71 and $661.33. The company is still confident that ore, in paying quantities, will soon be reached. A small amount of their stock will be placed on the market for the purpose of raising funds to prosecute the work The stock is unassessable, and will undoubtedly prove a good investment.

Connolly Mine.—The prospects of this company's property are very flattering, and extensive operations are being carried on. The principal mining is now being done on the 500 level, where they have a broast of ore eight feet wide and of high grade.

Eureka Con.—The Eureka Con. have completed their shaft from the 12th to 13th level, and are now drifting north for the mine. The upper levels continue to look well, and are furnishing the usual amount of ore. The furnaces are running nicely and making a large quantity of bullion.

The Jackson.—The Jackson mine never looked more promising. They are daily shipping to the Motamoras furnace about 45 tons of ore, which averages $70 per ton. From the present indications of the mine the stock ought to be worth double its selling price.

The Metamoras.—The Metamoras furnace is running

Geodetic Instruments of Precision at the Paris Exposition and in European Workshops.

[Read before the California Academy of Sciences, Feb. 17th, 1879, by PROF. GEORGE DAVIDSON.]

It is a fact familiar to those who have occasion to make use of instrumental contrivances, that novel methods are constantly being devised to meet new requirements or to lessen existing defects. As the delicacy and importance of any given work is increased, the observer soon discovers sources of error that had not been suspected, and finds errors that were veiled by the disposition of the relative parts of the instruments. Instruments of the higher class are too frequently at fault, but the ingenious observer is soon led to investigate the sources of trouble, and either to obviate them or to seek for the best instruments suited to his particular and peculiar duties. In the broadest view of the case we must not be confined to individuals or to nationalities, but aim only to obtain the highest mechanical design and workmanship. In the progress of the geodetic work of the United States, stretching from the Pacific to the Atlantic, and also northward and southward along the Pacific coast, there was furnished to me, among other instruments, one theodolite, of large size, which was subjected to the most rigid scrutiny to determine the flexure of the pillar plate, of the microscope arms, and of the telescope; also, the character of the graduation of the 20-inch circle, and various other points involving accuracy. Under ordinary circumstances the instrument would have passed muster for lines of moderate extent, but when lines of 160 miles in length were involved, it was essential to the integrity of the undertaking, that errors of even a second of arc should be avoided. At the distance of 160 miles one second of arc subtends four feet: a skilled observer can measure a much less quantity than one second, and certainly the instrument should afford the means of his measuring what he can see.

Fully alive to the importance of the subject, the Superintendent of the U. S. Coast Survey had determined that there should be made a careful examination and study of the instruments of precision, exhibited at the Paris exhibition for geodetic and astronomical work, topography and hydrography, for the telegraphic determination of longitude, etc. And, moreover, that the examination should be extended to the first-class workshops of Europe, where instruments of this character are manufactured.

It was desired to ascertain, if practical, whether the productions of European manufacturers were superior to our own; wherein lay any superiority, if found to exist; and in what consisted the peculiar merit of the work of any particular manufacturer.

As a mechanician seeking merely the trade secrets of the makers, I could not have expected to enter into any sanctum sanctorum; but upon a candid explanation of my purpose and instructions, I found nearly every workshop opened to me, and full and free explanations made to my inquiries. It would therefore be unjust to these manufacturers to severely criticise in public the character or even the minor defects of their instruments, or to make known the methods of their processes. These I received for the benefit of the Government, and whenever I mention any names here, it will be to commend their work; although many are officially commended that are not now referred to.

In previous experiments upon the larger and finer instruments, I have discovered errors of graduation and flexure of parts much greater than I had any reason to suspect; and I believe much greater and more serious than the makers had thought possible. This latter is the more readily understood when we reflect how few mechanicians are actually observers; and that it really requires long practice for the most skilled observer combined with fair mechanical instincts to discover and measure the minute and conflicting errors which are resultants of different infinitesimal, and perhaps unsuspected causes. As a rule, the observer makes his measures upon objects subject to many extraneous and disturbing causes, and whenever unsatisfactory results are obtained, he is very apt to attribute them to the unfavorable conditions of the atmosphere or to his own condition and temperament at the time; generally overlooking the fact that the instrument maker was quite as liable as himself to errors of judgment in the proportions and workmanship of the instrument used.

Setting aside for the present the peculiar adaptness and fitness of the observer for his business, we are necessarily interested in the requirements of geodetic operations and especially in the duties of the instruments by which these are satisfied. In all geodetic work, portability, accuracy and maintenance of instrumental adjustment are essential to rapidity of progress, to economy of expenditure in money and in personnel, and to precision in the results. Experience and theory teach us that in any given instrument, such as a theodolite for geodetic purposes, we need simplicity of design; fewness of pieces; harmony in the proportion of parts; accuracy of workmanship; superior graduation with adequate microscope micrometers; micrometer screws free from mechanical defects; commensurate optical conditions of penetration and power; sensitive and trustworthy levels; and the highest precision in all the bearings of the moving parts. Moreover, the general disposition of the parts should be such as to offer the greatest facilities to the observer, in order that he may make the necessary observations without fatigue or nervous strain.

Guided by these general considerations, I examined the fine collection of geodetic instruments exhibited by the Minister of War, many of the exhibits of private exposants, and some of the workshops of the manufacturers in Paris. After this I visited the principal manufactories of Geneva, Neuchatel, Munich, Vienna, Dresden, Berlin, Hamburg, Cassel, London and York. At the exposition I did not have the fullest facilities afforded me, and not only was I unable to get into one of the principal cases, but I was positively forbidden to continue my drawings; whilst one well known maker would not only not permit me to make any tests of the graduation of his theodolite, but would not allow me see his graduating engine. Outside of Paris I was permitted to see every graduating engine of the noted manufacturers, and afforded facilities for the examinations of their productions. But on account of the commercial depression which was overshadowing all business in Europe, as well as the United States, the number of the larger instruments on hand was very few. In some workshops I found that not over 20 per cent of the usual number of workmen was employed.

Besides the mechanical construction of the instruments, I was particularly anxious to study the capacities of the different graduating engines, in order to judge, in a measure, of the probable value of the results. The graduating engine is simply a mechanical tool with which we should expect to divide a circle of say 20 inches in diameter in 360 parts, with no greater an error than the 1-50,000 part of an inch or 4-10 of a second of arc in any one degree. The probable error of an experienced observer in reading the five minute graduations of such an instrument is about 1-10 of a second of arc, or the 1-200,000 of an inch. It is usually assumed that the graduation errors are not over one second of arc, and this is what the majority of instrument makers suppose or assert to be their average error in each degree graduation; but I am perfectly satisfied that even this limit of accuracy is rarely if ever reached. As a matter of fact I failed to learn from any manufacturer that he had ever tested a theodolite after graduation by measuring every five minute space on the circle, or even every degree; whereas in my previous testings of a 20-inch theodolite I had detected differences of 15 seconds between whole degrees, and errors of 5, 6 and 7 seconds in contiguous five minute spaces.

You can readily understand the almost multitudinous sources of error against perfecting a graduating engine; and the most skilled mechanicians find that it requires persistent labor and experiment for two, three or more years to approximately effect their purpose. Yet until we get a reliable graduation it is futile to seek for final accuracy in our measures; nevertheless all other sources of error should be reduced to minima, and the perfection of graduation persistently attempted. After a graduating machine has been made as nearly perfect as the means and skill of the mechanician can effect it, be carefully measures the different degrees, tabulates the errors, and generally constructs an error circle whose circumference is irregular in a certain proportion to the errors determined. This circumference is so connected with the tangent screw moving the graduate circle as to advance or retard the screw the exact amount of the error at any given point. This is one way of effecting the necessary correction, and is mentioned merely to serve as an illustration; yet in this method it must be evident that the retarding of a screw brings into operation any backlash that may exist even if it be almost practically infinitesimal.

Among the instrument makers I found the most positive and opposite views of practice; for instance, one believes wholly in automatic moving parts in the graduating engine, and makes every effort to secure uniformity of temperature, etc.; another scouts the automatic movement and does everything by hand, with or without much attention to change of temperature; one party believes in a steel cutting tool; another pins his faith upon his diamond cutter, etc. Many of the observers implicitly receive the dicta of the instrument makers, and but few make any exhaustive examinations for themselves. Among the tests which had been made by the Chief of the Prussian Geodetic Survey, between theodolites of a few of the best makers, there was a very close agreement in the probable error of the systematic errors, but the probable error of the irregular errors was only half as great for the Wauschaff circles as for the others. Without here mentioning the names, I may state that from the character of the instruments examined, I recommended the Superintendent of the Coast Survey to have circles graduated by five of the best makers, and test them as I had tested the 20-inch theodolite referred to. For where mechanical skill is good and apparently nearly equal, it would be vain to attempt to decide by simple inspection or upon a maker's reputation, although upon these merits alone awards were made at the exposition.

After the instrument maker has effected the division of the graduating circle into degrees, the sub-division into 2-minute, 4-minute, 5-minute, or 10-minute spaces is sometimes made by verniers suitably divided, but frequently the coincidence of the lines of the vernier and the circle is determined by bringing the ends of the lines together, and judging by the eye whether one is truly a prolongation of the other. The Reposolds certainly appreciated this source of error and had in a great measure successfully overcome it. Some of the graduating engines examined had been made and in use from thirty even to fifty years; now considering the great advance in the construction of instruments of precision in that time, it is hardly too much to ask that this special mechanical tool should be perfected. Of course there are more recent efforts but not yet notably perfected. It offers to our younger skilled mechanicians a very delicate problem upon which to try their ingenuity, skill and patience; with such a tool superior to those of their competitors, they may be assured of a fair income from its work alone, and an enviable reputation.

Of the larger theodolites which I had an opportunity of examining, the best was by Brunner. It combined fewness and simplicity of parts, and fair harmony of proportion, yet I should certainly doubt the adequacy of its optical power for long lines; it reads by four verniers instead of three, involving more labor, and less reading points on the circle; whilst the observer must be placed in a constrained position because the horizontal plane of the telescope is only about two inches above the reading microscopes. Moreover, the circle (instead of the whole instrument,) is changed for new positions and clamped by three screws in each position. Should the surface planes of contact be warped, this clamping would warp the circle in each new position and thereby introduce error. This method was devised about 20 years since, and soon abandoned; it is now the fashion.

In the evident desire to obtain compactness and simplicity, the instrument is not adapted to the observing of azimuths by means of a close circumpolar star, because the telescope cannot be elevated. Instead, the transit instrument must replace the theodolite for that purpose, whereby the possibility of error is introduced in occupying the identical station; and even if this be granted, the labor is increased and extra time consumed.

Fashions prevail among instrument makers and observers just as we find a change of opinion upon the question of refractors and reflectors. At one time it seemed as if the prismatic telescope was to carry everything before it, and I find many manufacturers and observers yet strongly in favor of that form. It certainly has the decided advantage of comfort to the observer; but from personal experience, and from conferring with such observers as Plantamour, it seems that the system necessarily involves "flexure" or deformation of the prism, notwithstanding the numerous and ingenious efforts made to secure it properly in position. Of course some manufacturers insist that their special methods of securing the prisms are infallible; but the observer is the final judge of their failures. In the highest character of work I should certainly not use them; whilst for the secondary works it seems hardly necessary to increase the number and intricacy of the parts.

A prevailing fashion at present is to introduce reversing apparatus and counterpoises, even in theodolites with circles of eight inches in diameter. This is as complete a wandering from simplicity as can well be imagined, and must certainly lead to grave errors. It is well known that by moving a telescope in altitude by means of the usual slow-motion screw, the tendency is to raise the transit axis pivots, but as the weight of the telescope is too great to be lifted clear of the Y's, the pivot is moved up one side of the sloping Y, and the telescope thereby changed in azimuth. Now, if the weight of the telescope be counterpoised by springs, the pivot is lifted still higher and the resulting change in azimuth becomes greater. Not only that, but the intricacy of the adjustment thereby introduced, conflicts very much with the hearings of the vertical axis. I saw no form of reversing, that should be applied to any first class theodolite, or to any theodolite which might be used at a distance from the workshop of a skilled mechanic. The same amount of labor otherwise expended upon the same instrument, would largely increase its value for honest work. This form, as well as the prism telescope, must however be demanded by observers or the makers would hardly continue their manufacture.

Another fashion that seems to prevail is the use of microscope micrometers upon small theodolites of eight inches diameter, and even in some cases of only six inches. These microscope micrometers read the circle to one or to two seconds; but in every such case the telescopic power and the transit axis level were vastly inferior to such delicacy, and therefore the contradiction existed that the instrument maker expected the observer to measure what he could not see. In fact, I think it may be safely asserted as a rule that the telescopic power of all the instruments examined was inferior to the other parts.

And still another fashion is in the use of the universal or Altazimuth instrument. The combination of two or more instruments for different purposes into one instrument for all the required purposes is difficult and doubtful even in machines of industry; but when every new piece and movement introduces a fresh source of error into a delicate instrument where the constant study should be really to decrease them, the combination must be clearly shown not only to possess freedom from additional errors, but to give better results or as good results as two different and separate instruments at less cost of construction, less weight for transportation and mounting, and greater rapidity of manipulation. For certain classes of work, the universal instrument has, without doubt, some decided advantages; but for such work as is demanded in the primary and main triangulation of the United States they are essentially unsuited. Nor would our surveys willingly adopt the eccentrically placed telescopes of the theodolites used in the Prussian Geodetic Survey, although the character of that work stands very high; if any series of observation is broken it cannot be utilized without extra calculation; and a loss of time means a loss of money. The multiplicity of parts in some of the instruments on exhibition was astonishing. I was attracted by the complication of an instrument having a circle of about eight inches diameter, and although I could see little more than one side of the instrument I counted no less than 93 screws of all kinds, whilst others seemed evolved and contrived from the inner consciousness of some closet professor.

In one large combination instrument in the exhibition, there were, among other curious features, two small lamps for illuminating the horizontal circle under the three microscopes; one for the telescope, and one for reading the level and the two microscopes for the vertical circle, together with a multiplicity of mirrors to reflect the lights. No matter howsoever small the heat of the flames might be, here was the introduction of sources of error that would tend to complicate and mask the other defects of the instrument.

I had the opportunity of studying many of the recent and varied forms of portable transit instruments. Some there were that never should have been permitted to leave a workshop; others aiming at great stability by the use of very heavy cast-iron stands, yet introducing an element of error in having their adjustments for level and azimuth at the base. This seems very much like erecting a great solid building upon a movable foundation. It is granted that in the usual form of movable Y's for the adjustment of the transit axis level and of azimuth, two fertile sources of error exist, but many years since I readily and successfully overcame the difficulty by tightly clamping either movable Y after the last mechanical correction has been made to the adjustments. Troughton and Simms have in part since used a similar application. The frames of the later Coast Survey transit instruments are emphatically portable from their form and weight of metal; their telescopes have generally greater light-collecting power than the portable transits examined, whilst the character of the results is fully established by the rigorous method of discussing them. By the adoption of four foot-screws I have secured remarkable firmness; whilst the double frame gives not only great facilities for preliminary adjustments in the meridian, but enables the transit to be used for a latitude instrument by the Talcot method. Some of the portable transits in Europe hardly bear out that character, and would not be adopted in the mountains where our geodetic work is being carried; it was very evident that cast-iron was cheap, transportation easy, and time no object. And I found severer criticisms than mine passed upon particular instruments (designed for great surveys) by some whose opinions have much weight in the geodetic world; whilst one well known observer confessed, that were he to design a new instrument it would not have the form of that which he had planned, constructed and already used.

Although I made few efforts to examine the manufacture of lenses for telescopes and microscopes, those which I did see were generally of superior character. I was very much impressed with the thorough skill and knowledge of Shroeder, of Hamburg, who was making the lenses for the 15-inch equatorial of the new Potsdam observatory. An examination of some of his smaller instruments revealed marvelous precision of figure, whilst his means of testing the curvature of the lens was beyond anything I had seen or known. The computations for the curvatures of the lenses are very elaborate and exhaustive.

Without going into details of telegraphic longitude apparatus, electrical clocks and chronometers, etc., I may mention that I examined the base apparatus of Brunner, being constructed for the Spanish Geodetic Survey; and had the greatest pleasure in examining the original base apparatus of Bessel in the Prussian geodetic office. The Brunner apparatus aims at the simplicity of the Borda thermometer, and is therefore composed of two four-meter bars of different metals, having largely different coefficients of expansion. The lower bar is platinum; immediately above it is the brass bar of the same cross section. At one extremity of the compound, or rather composite bar, the two bars are joined, but are free towards the other extremity. At the free ends the upper bar has a slot in it that receives a piece soldered to the lower bar, whereby the upper surface of this piece is flush with the upper surface of the brass bar. Upon one is cut a series of graduated lines; upon the other a vernier. When the bars expand or contract through increase or decrease of temperature they do so unequally, and the difference of that change is read and is determined by the scale and vernier.

The base bars of Bessel are four in number, and each composite bar is formed of two bars of different metals of different rates of expansion for equal increments of heat. In this case the lower bar is iron and the upper is zinc. One end of each system is formed by the junction of the two bars, and thence the bars are free. Instead of a scale upon one and a vernier upon the other, the zinc bar terminates close to a small projection upon the upper surface of the iron bar, and the difference of expansion was measured by the insertion of long graduated wedges of glass in the space between the end of the zinc bar and the iron stud.

Either of these forms of apparatus has great merit in the extreme simplicity of the form and fewness of parts, and it appears to me that with thorough skill in the observer, accuracy of comparison with the given standard bar, simplicity and stability of the supports, and the proper means of effecting the contacts, the method is susceptible of great accuracy. But I was very far from being satisfied with the character of the

supports and the methods and appliances of measurement. These, however, I discuss fully in my official report to the Superintendent of the Coast Survey.

Without detaining the attention of the Academy any longer, I may mention, in brief, the general conclusion to which I arrived. While I saw much of deep interest, there was no single instrument that I would unreservedly recommend for adoption in its entirety. What I principally learned was really *what not to copy*. And whilst awarding high credit to the instrument makers of Europe, and keenly alive to their courtesy, I am convinced that we do not need to go to Europe for geodetic instruments, although we should possess copies of their finest efforts for comparison with our own. With our own observers and mechanicians working in harmony and striving to attain the highest excellence, I firmly believe that we are fully competent to lead in this scientific effort. Both parties fully appreciate the fundamental requisites to success, and the character of the geodetic work of the United States demands that the mechanical means shall be adequate to the delicate manipulation and requirements of the most skillful observers.

The Cone-bearers, or Evergreen Trees of California.—No. 6.

[Written for the PRESS by J. G. LEMMON.]

Juniper. Yew. Nutmeg and Joint-Stem.

Tribe III. (Last tribe of the first great order of *Pinaceæ*), improperly called "red cedar" at the East. *Junipereæ*, Juniper family. A large and distinct family of very slow growing trees, forming but one genus in all the world. Fruit a consolidated cone or closed berry, called, scientifically, a *galbulus*, not opening at maturity; leaves acicular (needle-shaped) or scale-like, opposite or in whorls of threes, closely imbricated; pith of the limbs very eccentric, *i. e.*, the limbs take on material from one side.

Only genus *Juniperus*, from *juvenus*, a child, and *pario*, to prevent; the berries from time immemorial have been used to procure abortion; two species and one marked variety of another species in California.

1. *Juniperus occidentalis*, Hook. "Western juniper," a decrepit tree, sparsely found on the eastern slopes of the Sierra, generally only a few feet high, however large at base, but in Oregon forming trees of the largest size and of symmetrical proportions. Berries small, bluish black, pulpy, very resinous; leaves in threes, or often in pairs.

2. *Juniperus Californica*, Carriere. "California juniper." A stout, many-branched shrub, or occasionally a small tree 16 to 20 feet high, sparsely found from Mount Diablo southward, on dry mountain slopes. Berries larger, one-half inch long, reddish-glaucous, sweetish, used by southern Indians for food; leaves nearly always in threes.

3. *Juniperus Sabina*, L, variety, *procumbens*, Pursh, "Rock juniper"—"Creeping juniper." A prostrate, creeping shrub, carpeting dry rocky ridges in certain few localities in the Sierra; berries small, resinous; leaves in pairs of two sorts; on sterile plants, acerose, one-half inch long; on fertile ones, simple, oppressed scales. This genus ends the great order of *Pinaceæ*, comprising the most of our conifers. The three other orders, being only sparsely represented here, one of them not at all, will require but little space for description.

Order II.—Taxaceæ. Yew Family.

A small order of slow-growing, heavy-scented trees, chiefly found in northern Europe and Asia. Fruit with cone characters nearly obliterated, more or less drupe-like, resembling a plum, containing but one seed, naked above; leaves two-ranked, lanceolate, acute. All parts of the tree exhaling a disagreeable odor. Two genera, each with one species, in California. First genus *Taxus*, Gr. *taxon*, a bow, anciently used in archery. "Yew Tree." Fruit shaped like an acorn cup, becoming a pulpy dish, holding a small upright seed.

Taxus brevifolia, Nutt. "California yew." A small tree of limited localities in the Sierra, becoming larger in the Cascade mountains of Oregon, Fruit very small, one-quarter inch across, viscid, edible; leaves dark green, on short foot-stalks; timber hard and heavy. The twigs of this yew are supposed to be poisonous to stock; will some reader having knowledge of the trees please report?

False Nutmeg Tree.

Second genus *Torreya*. A commemorative genus, dedicated to John Torrey, the most distinguished of American botanists. Fruit, a large closed berry, resembling a nutmeg. This is a small genus of only four known species, but, curiously enough, they are scattered at nearly equal distances around the northern hemisphere, and found always in company with a solitary species of *Taxodiæ*, the latter either living or fossil.

Torreya Californica, Torr. "California nutmeg," A beautiful tree, 40 to 60 feet high, found accompanying the redwood of the coast and the big tree of the Sierra. Fruit, rugose, wrinkled, one to one and a half inches long, resembling a nutmeg, but having none of its qualities; leaves two to three inches long, dark green, decurrent and very sharp pointed.

Order III.—Gnetaceæ, Joint-Stem Family.

A very small order of shrubby plants, excluded from the *coniferæ* by most writers and having scarcely any outward resemblance to the rest of the class of gymnosperms, being jointed like the horse-tail or scouring rush, and often with net-veined leaves, both characters connecting this class with the endogens below it, but its naked seeds in a scaly cone, and its resinous juice, compel its classification with the *gymnosperms*. Shrubby, desert-loving plants, mostly confined to the arid plains of Asia. One genus of two species in the Great Basin, and barely reaching the limits of our State.

The generic name *Ephedra* is the Latin for horse-tail, the common scouring rush.

1. *Ephedra antisyphilitica* ——? "Washoe joint-stem." Found on the eastern foothills of the Sierra. Young stems slender, straw-colored, in fascicles of more than three; cones ovate, nine-half inch long; leaves few, small, papery.

2. *Ephedra trifurca*, ——? "Colorado joint-stem." A similar bush of the Mohave and Colorado desert, but with stems, leaves and cones always in whorls of threes.

This species concludes the description of all the gymnosperms indigenous to California, no representative of the curious fourth order, *Cycadaceæ*, is found growing north of the tropics, except in greenhouses.

Readers familiar with the Eastern forests and with the scientific names of the trees, will notice the absence of all the conifers of that region, some of them so distributed and adapting themselves to such different circumstances that you think they might grow here. Other readers may be misled because we call some of our trees, colloquially, by the same names as others of the East. They are very distinct, however. It is resemblance, not identity of species. And here recurs the often-enjoined lesson, that scientific names are the only ones that really distinguish. The vernacular of all countries is limited, crude and conflicting. We have not an identical species of the nine Eastern pines—White, Broom, Loblolly, Pitch, Yellow, Southern, Jersey, Red and Scrub. Not one of their six spruces and firs—Hemlock, White, Black and Norway spruce, and Fir and Double Balsam. Neither of their tamaracks (nor any other *true* ones). We have not the same species of arbor vitæ, cypress, redwood, juniper, yew, nor nutmeg.

Ours is a peculiar climate and soil, and their productions correspond, and in nothing more strikingly and beautifully, than in our mountain forests of cone-bearers.

And now if I have aided my California readers in better questioning and knowing the trees of our noble forests, I am satisfied with the travel, research, study, time, labor and stationery it has cost.

[Concluded.]

Useful Information.

Hints for House-Cleaners.

We give below a few hints which may prove useful to housekeepers:

Soot falling on the carpet from open chimneys, or from carelessly handled stove pipes, if covered thickly with salt, can be brushed up without damage to the carpet.

A little spirits of turpentine added to the water with which floors are washed, will prevent the ravages of moths.

When carpets are well cleaned, sprinkle with salt and fold when laid, strew with slightly moistened bran before sweeping; this, with the salt, will freshen them wonderfully.

Fuller's earth, mixed to a stiff paste with cold water, spread on the carpet, and covered with brown paper, will, in a day or two, remove grease spots; a second application may be necessary.

Spirits of ammonia, diluted with water, if applied with a sponge or flannel cloth to discolored spots in carpets or garments, will often restore the color.

A paste made of whiting and benzine will clean marble, and one made of whiting and chloride of soda, spread and left to dry (in the sun if possible) on the marble, will remove spots.

Paint, splashed upon window-glass, can be easily removed by a hot solution of soda.

Use kerosene and brick-bath or lime, to scour zinc, tin or copper; wash in hot suds, and polish with dry whiting.

To give glass great brilliancy, wash with a damp sponge dipped in spirits, then dust with powdered blue or whiting, tied in a thin muslin bag, and polish with chamois cloth.

A flannel cloth dipped in warm soapsuds, then into whiting, and applied to paint, will instantly remove all grease and dirt. Wash with clean water, then dry; the most delicate paint will not be injured, and will look like new.

One pound of copperas dissolved in one quart of boiling water will destroy foul smells.

Powdered borax scattered in their haunts will disperse cockroaches.

Plaster of Paris mixed with gum arabic water makes an excellent white cement, but must be used immediately, as it hardens quickly. A mixture of five parts gelatine to one of acid chromate of lime, applied to broken edges, which should be pressed together and exposed to the sunlight, makes an insoluble cement.

To whiten walls, scrape off all old whitewash, and wash the walls with a solution of two ounces of white vitriol to four gallons of water. Soak a quarter of a pound of white glue in water for 12 hours; drain and place in a tin pail, cover with fresh water, and set the pail in a kettle of boiling water. When melted, stir into the glue eight pounds of whiting, and water enough to make a mixture as thick as common whitewash. Apply evenly with a good brush; if the walls are very yellow, blue the water slightly by squeezing in it a flannel bag containing some powdered blue.

To clean matting, wash with a solution of one pint of salt to four gallons of water, and wipe dry immediately.

To clean oilcloths, wash always with warm milk. Once in six months scrub with hot soapsuds, dry thoroughly, and apply a coat of varnish. They will last as long again.

A little kerosene added to stove-polish improves the luster. Apply while the iron is warm.

To remove spots from furniture take four ounces of vinegar, two of sweet oil, and one of turpentine; mix and apply with a flannel cloth.

Gum camphor wrapped in paper and laid around sugar barrels will disperse ants.

COLORING METALS.—A foreign paper gives the following: Metals may be rapidly colored by covering their surface with a thin layer of sulphuric acid. According to the thickness of the layer and the duration of its action there may be obtained tints of gold, copper, carmine, chestnut brown, clear aniline blue, and reddish white. These tints are all brilliant, and if care be taken to scour the metallic objects before treating them with the acid, the coloring will suffer nothing from the polishing. On making a solution of 640 grains of lead acetate in 3,450 grains of water and warming the mixture to 88° or 90°, it decomposes and gives a precipitate of sulphuret of lead in black flakes. If a metallic object be immersed in the bath, the precipitate is deposited upon it, and the color produced will depend on the thickness of the deposit. Care must be taken to warm the objects to be treated gradually, so that the coloration may be uniform. Iron treated in this way has the aspect of bluish steel; zinc, on the contrary, becomes brown. On using an equal quantity of sulphuric acid instead of lead acetate, and warming a little more than in the first case, common bronze may be colored of a magnificent red or green, which is very durable. Very beautiful imitations of marble may be obtained by covering the bronze objects warmed up to 100°, with a solution of lead thickened with gum tragacanth, and afterwards submitting them to the action of the precipitate spoken of above.

IMPORTANCE OF COOL-GRINDING OF FLOUR.—Mitcherlich and Crocker have shown that wheat in which sugar was proved to be absent before sending it to the mill, yielded, after being ground, four per cent. of it. Starch was thus transformed into sugar, which could not be done otherwise than through the internal action of the gluten aided by superabundant moisture. The mutual action of the gluten and the natural moisture of the flour seem often capable, at common temperatures, of slowly bringing about this injurious change. But when the flour comes out hot from the stones and is left to cool gradually in large heaps, decomposition quickly sets in, starch is changed to sugar, and (when kept warm long enough) the sugar into alcohol, while if the temperature is continued long enough above 60° Fahr., it advances rapidly to the souring stage. These facts form a strong argument in favor of cool grinding.

POISONOUS COLORS.—According to the *Chemical Review*, energetic steps are being taken in Switzerland against the use of poisonous colors. The Governing Council of Zurich has prohibited the use of all coloring matters prepared from the compounds of the metals lead, arsenic, copper, chrome, zinc, antimony, bismuth and mercury, for decorating articles of consumption or of clothing, or their materials; also paper for wrapping up chocolate, coffee, tea, chiccory, tobacco and eatables in general; toys, covers and cushions of children's carriages, carpets, curtains and window blinds, lamp screens, wafers, and table services. Poisonous organic matters, such as gamboge, picric acid, the aniline colors, especially magenta, are not to be used for coloring articles of food or drink, such as confectionery, jams, syrups, wines, etc. The same rule applies to the phenol colors. Imported articles containing such poisons may not be sold.

IMMENSE PHOTOGRAPHS.—At a recent meeting of the Berlin Association for the Promotion of Photography there were exhibited some remarkable photographic pictures taken by Herr Holtermann, of Sydney, Australia, and which, in point of size, probably far exceed anything thus far accomplished in the art. They were mounted on an endless band of paper, strengthened by linen, and were nearly 100 feet in length. Among them were two colossal panoramas of the cities of Sydney and Melbourne, each made up of about a dozen sheets, and very skillfully joined together, the separate pieces harmonizing perfectly in tone and depth. One picture of the list, and which had obviously been printed from a single negative, was about five by three feet in size.

TO CHILL CAST IRON VERY HARD.—Use a liquid made as follows: Soft water, 10 gallons; salt, one peck; oil vitriol, one-half pint; saltpeter, one-half pound; prussiate of potash, one-quarter pound; cyanide of potash, one-half pound. Heat the iron a cherry-red and dip as usual, and if wanted harder, repeat the process.

Good Health.

Some Hints in Regard to Diet.

In Dr. Hall's *Journal of Health*, a few years ago, the following statement of the amount of nutriment in various articles of food was given:

"Raw apples, 10%; boiled beans, 87%; roasted beef, 26%; baked bread, 80%; butter, 96%; boiled cabbage, 7%; raw cucumbers, 2%; boiled fish, 20%; fresh milk, 7%; roasted mutton, 30%; roasted pork, 24%; roasted poultry, 27%; boiled potatoes, 13%; boiled rice, 88%; sugar, 96%; boiled turnips, 4%; roasted veal, 25%; and boiled venison, 22%."

From this statement of Dr. Hall's a correspondent of the New York *Sun* makes the following deductions:

"The cheapest articles of food, except butter, are the most nourishing. A pint of white beans, costing a few cents, contain the same amount of nutriment as 3½ pounds of prime roasting beef, which is 12 times as expensive. Furthermore, a pound of Indian meal will go as far as a pound of fine flour."

In alluding to the above, the Boston *Journal of Chemistry* says:

"We call it a loose statement, and so are all the statements made in various books in regard to the comparative nourishing qualities of various kinds of food, as they are all based on some false premise; some, for instance, on the percentage of nitrogen in the food, others on the amount of water in it, etc. The result is an erroneous comparison, and the deductions drawn must be false. Thus in the above table, sugar is 96%, and turnips 4%, making 24 pounds of turnips equivalent to 1 pound of sugar; rice 88%, and roasted beef 26%, making 1 pound of roasted beef not much more nourishing than 4 ounces of boiled rice. The whole assertion is simply absurd and the table worthless, as every one will maintain who properly attends to the duty of selecting his food judiciously in regard to the wants he feels.

"We deliberately call it a duty to be careful in selecting our food; we even go further, and call it a crime not to feed well, or to be negligent in our selection, eating or drinking things we dislike, or, what is worse than all, eating when we have no appetite, simply because it is time for meals."

In speaking of a corn dict the same paper remarks:

"Very few constitutions can stand a corn diet. In most cases corn has a tendency to sour on the stomach, and by its continued use, chronic dyspepsia and premature death results.

"Man, and especially civilized man, needs a variety of food. The man who does a great deal of brain work requires different food than the man who only works with his muscles, as the one consumes more nervous material, and the other more muscular; and as different as the chemical composition of the brain and nerves is from that of the muscles, equally different must be the character of the food needed to supply the waste."

Carbolate of Soda for Whooping Cough.

Dr. Pernot describes in the Lyons *Medical Record* a very successful treatment of whooping cough with carbolate of soda. He places the carbolate of soda in a small porcelain crucible held above the flame of a spirit lamp, which keeps it in an unvarying temperature as long as wished. As the carbolate of soda becomes volatilized, the atmosphere of the sick room is impregnated with the vapor of carbolic acid.

When the crucible and lamp are not at hand, a satisfactory substitute is found in a fire-brick heated enough to vaporize the carbolate. In numerous cases the following results have been obtained.

1. A notable diminution of the paroxysms of coughing after from two to ten days' treatment. 2. Less labored and painful respiration. 3. Shorter duration of the paroxysms of coughing. 4. The most confirmed attack of whooping cough remains *in statu quo* from the commencement, and it always appeared to him to diminish more or less rapidly, but always in a time relatively short to its usual duration.

The vapors of carbolate of soda have valuable disinfecting and antiseptic properties

It is worthy of note in this connection that the fungoid origin of whooping cough, asserted some years since by M. Svetzerich, seems to be confirmed by the recent researches of M. Yschamar, who says he has found certain lower organisms in the spittle of whooping cough patients—organisms not met with in any other disease accompanied by cough and expectoration. He claims further, that the organisms in question are identical with those which, by their agglomeration, form the black points on the skins of oranges and the parings of certain fruits, especially apples. Thus, M. Yschamar, by inoculating rabbits with this dark matter, or even causing it to be inhaled by men, produced fits of coughing several days in duration, and presenting all the characteristics of the convulsive wooping cough.

THE ORANGE.—The orange is very easily digested, admissible in health and disease, and one before breakfast will often prepare the delicate stomach for a good meal better than anything else.

The Week.

Lent has come in very quietly, and it seems as if its approach had brought a dullness in all matters of general interest. In most of the agricultural sections, the farmers are too busy putting in their crops to send us news, although from some parts of the north complaints of too much rain may be heard. The stir among mining circles comes principally from the hydraulic claims. Oregon exults over a new-found El Dorado along the Snake, and the placers of Nevada and Butte counties are also producing bountifully. Stocks are dull and buyers cautious. The interest in the Chinese question becomes more intense as the close of congressional session approaches. Disasters and accidents have been numerous during the week. Various parts of this State, the western coast of South America, and some of the Southern States, have experienced shocks of earthquake. The boiler explosion at Stockton, resulting in such terrible loss of human life, can only receive the old explanation of "carelessness." The Indians have risen in the North, and at the Black Hills, and are plundering and murdering on all sides. Floods, too, are desolating the northern part of the State, and Oregon. The insurrectionists in Central America are being worsted by the Government troops. France and England have found it necessary to send war vessels to Egypt to prevent the Khedive from compromising international interests by his misgoverument of that country. The weather is warmer and drier, and spring will open with bright, sunny days.

THE draft of negro laborers to Texas has impelled the Legislatures of Alabama and Georgia to impose a license tax of $100 upon every person soliciting people to emigrate from those States.

SEVERAL lines have been got around the sunken steamer *El Capitan*. She will soon be raised and taken to Oakland Point, where all necessary repairs will be made.

Where to Invest Money in Mining.

In reply to the letters that frequently reach us inquiring as to the best openings on this coast for the investment of money in the business of mining, we may say, it is not easy to point out these openings except with much qualification and in a very general way; so much depending always on the means and purposes of the party desiring to invest and the circumstances that surround each particular case. It can hardly be affirmed that any one section of the coast possesses such manifest advantages over every other as should determine this question, irrespective of the above considerations. To answer these questions intelligently and properly, one requires to be informed whether the inquirer is a capitalist or a working man; whether he wishes to put in his own labor, to be on the ground and supervise matters in person, or whether he is simply seeking a safe and profitable investment, leaving the management of the business to others. Where there is a preference for engaging or investing in any particular section of country or special branch of mining, it would be well also to indicate the same.

To men of limited means, who would like to obtain proprietory interests in mines, and with whom the certainty of moderate profits is paramount to large gains with corresponding hazard, California would seem to offer the best field west of the Rocky mountains; this being especially true if they desire to engage personally in the business, making permanent homes in the mining regions. For this opinion we have not here room to assign reasons in detail: the generally reliable character of the mines, the facility with which they can be reached, opened and outfitted, the cheapness of labor and supplies, the good state of society, insuring ample protection to person and property, and the superiority of the climate constituting, in brief, some of the principal arguments in its favor. The foothills of the Sierra Nevada and other outlying ranges of mountains, the sites of the several California gold fields, form one of the most beautiful, healthful and every-way attractive regions under the face of the sun. Apart from their mineral resources, they offer the greatest possible inducements for settlement by men desirous of obtaining pleasant and comfortable homes.

Then, in embarking in this industry, the adventurer has here a greater variety as to the kind of mining he may choose to engage in, there being the several branches of placer as well as vein operations from which to select, according as his means may warrant or other conditions make preferable. While there is now little chance for securing rich claims and making large wages in the placers of this State without the employment of considerable capital, it is still possible for the right kind of a man, though he have but little money, to get hold of claims that, even from the first, will afford living wages, and which, through the use of small means and under the diligent application of his own labor, can eventually be made to pay steadily and handsomely, if not very largely. The opportunities for accomplishing this much are, in fact, very good in many parts of the California mines, the central and more northerly sections of the State presenting perhaps more of these opportunities than the districts farther south.

As we had occasion not long since to speak of the inducements held out for the investment of capital in the quartz mines of Sikiyou and the hydraulic deposits of Trinity counties, we will, without stopping now to enlarge upon the resources of this extreme northern section of the State, briefly remark upon some points farther south, that seem to present openings that ought to attract the attention of parties desirous of investing in either quartz, drift, or hydraulic mining. In Shasta county, some good chances could doubtless be found for engaging in quartz mining. Plumas offers a fair field for vein and drift mining, the seasons, owing to the depth of the winter snows, being rather short for successful hydraulic operations. In Butte, while there is little chance for inaugurating further hydraulic washing, all the water available here being already appropriated, there are still opportunities in this county for opening up both quartz and drift mines, with good promise of success.

There is not, in the State, a county that more strongly claims the attention of parties seeking a legitimate field of investment than Sierra, and what we say of this county is largely the result of recent personal observation; not that the mineral deposits here were originally any better than throughout the tier of counties farther south, but simply because they have been less developed. This field is full of unaccomplished work, because it has been neglected. There is here material for prosecuting every form of gold mining known in California. Along Slate creek and its tributaries, have been lodged immense quantities of hydraulic tailings, that at small expense could be moved and subjected to a profitable re-washing. At Brandy City, and about Milton, are large deposits of auriferous gravel that could be run off by the hydraulic process to good advantage; those at the former place being partially utilized, but requiring some further money aid to make them fully available, while the deposits at Milton have never been worked, only prospected enough to indicate for them a great probable extent and richness. At this latter place are a number of fine quartz lodes, affording unmistakable evidence of good paying qualities, but, like the gravel, but slightly opened. The owner, Dr. Holdsworth, an old resident of Milton, would like some one having a little money to come and look at them. He does not want to sell them, but would convey to any party a large interest in them on condition of their putting up a small mill to work their ores. He would only ask for a prospecting mill at the start, satisfied that one of much greater capacity would soon be required; and it looks to us as if there were pay ore enough in sight here to run a hundred stamps for some years. Near Forest City, about Alleghany, and at many other points in this county, are found the remains of the old buried rivers, that afford good drift diggings.

In the counties south of Sierra, the opportunities for the inauguration of new hydraulic enterprises are limited, because of the inadequate supply of water for additional washing. But these counties abound with excellent opportunities for engaging in both quartz and drift mining, with occasionally a good chance for re-washing the hydraulic tailings, that in some localities have accumulated in great quantities. Some of the old bars and sections of the river beds are also being worked here by such improved appliances and methods as promise to make these ventures largely remunerative, the places favorable for this class of operations not being as yet by any means monopolized.

In saying so much of the openings that exist in this State for engaging in the business of mining, it must not be inferred that we wish to disparage the opportunities presented by the other States or the Territories lying on this slope of the continent, each of which contains a large scope of mineral lands, and some of which present, no doubt, greater attractions to the speculative and adventurous, than can be claimed for California. It is to that class of investors, with whom security to person and property, and certainty of return, are controlling considerations, that this State especially commends itself.

The East and the West.

There seems to be an awakening interest at the East in mining west of the Rocky mountains, and it is important to the whole country that that interest should be judiciously directed, encouraged and protected. Hundred of impecunious and unreliable adventurers with bonds or deeds to wild cat mines in their pockets, have gone from California, Nevada, Idaho, Utah, Colorado, Montana and Wyoming, to the populous and speculative cities of the Union to *sell* their locations, and the purchasers thereof, at one and the same time. We hear of sales having been made of Bodie locations and Bodie stocks, at New York city, which have not, as yet, shown any value whatever. We advise our Eastern friends to go slow; to thoroughly examine properties offered them before purchasing, and not to pay enormous prices for mere locations, or for mines that can be purchased at San Francisco, or on the ground for a comparatively small sum. There is still another class of mining operators who have their agents at the East, and who strike harder and deeper into the coffers of the capitalists there than the one we have adverted to. This class run the big assessment mines of the country and, through the force that wealth and power bestows, are foisting mines on the Eastern market that will eventually, in the end, cause the people there any amount of trouble and loss. The gold and silver mines west of the Missouri river yield over $100,000,000 annually, and profitable purchases can, with care, be effected and princely fortunes be derived from legitimate mining; but we feel constrained to caution our Eastern friends against being taken in by the adventurers who are now pouring in upon them. There never was a better time for engaging in actual and *legitimate* mining on this coast than the present; and while we feel called upon to put people abroad on their guard against the venders of worthless properties, we are free to admit that a very large proportion of those offered Eastern investors are in the hands of honest and honorable men, and really possess a great deal of merit. What we desire to enforce upon Eastern communities is the necessity of discriminating between these different kinds of men and properties.

WHERE UNCLE SAM KEEPS HIS TREASURE.—The vaults of the U. S. Treasury, which now contain many millions in gold and silver, have, as may well be supposed, been made as nearly fire and burglar proof as possible. The doors are a curiosity, and were made in Boston. The locks are chronometer, of the latest pattern. One man, and one man only, in the building can open the vaults. He can open them only on a given minute—then or not at all. It takes 500 men to do the business of the Treasury Department in New York. The highest office is said to be worth $35,000 per year, the lowest $10 a week. It took five barrow loads of gold to answer a single order lately, and that sum was wheeled from one bank to another. Though already so plethoric, these vaults are constantly receiving additional deposits of specie, $500,000 in silver having been amongst receipts of recent date.

A New Amalgamator.

John B. Reynolds, of this city, has recently patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, an improved apparatus for amalgamating the precious metals, by means of which every particle of ore is brought in contact with the mercury, so as to effect a thorough amalgamation. It consists in the use of a series of cylinders, in each of which a certain quantity of mercury is placed. The pulp is forced by a jet of steam into these cylinders and into the mercury, being heated and agitated at the same time. As it rises up through the mercury, another spray jet of steam is forced against the pulp, before or after it rises out of, or on the surface of the mercury, thus breaking up any lumps or masses of pulp, and agitating the pulp and mercury together. The pulp passes out of the top of the cylinder, and another jet of steam forces it down under the mercury in the next cylinder. Any number of these cylinders and steam jets necessary may be used. The process is continuous, the pulp being violently agitated while entering each cylinder and receiving an accession of heat from fresh jets of steam, as it passes from one to the other. Means are provided for controlling the supply of steam, preventing leakage, and for cleaning up the cylinders.

The operation of the device is as follows: The pulp from the batteries is admitted into the tank, where its consistency may be regulated with more or less water, as desired; but usually it will come from the batteries in proper condition for passing through the amalgamating apparatus. The pulp is allowed to flow from the tank down a pipe, at the lower end of which is the pipe leading into the front cylinder. Steam is turned on from the branch steam pipe through the nozzle into the pipe, which has the effect of forcing the pulp through the pipe into the cylinder under the mercury in said cylinder. The action of steam under these circumstances is to draw the pulp down from the tank and force it through the pipe, at the same time stirring and agitating it in a violent manner, so that it enters the mercury in the cylinder in a finely disseminated condition, most favorable for amalgamation of the precious metals contained in said pulp.

The mercury in the cylinder only occupies a portion of the space in said cylinder. As the pulp is forced in under the body of mercury, it rises through it, and on its way up, meets the spray from the spray nozzle, which violently agitates both the mercury and pulp, thus breaking up any masses or lumps of pulp which may have escaped the action of the first injecting.

As the pulp continues to be forced in, it rises to the top of the cylinder over the mercury and passes out into another pipe. As it reaches the end of the short arm of said pipe it meets the downward descending jet of steam from the nozzle on the end of the branch pipe, which forces said pulp down said pipe and into the next cylinder, under the mercury in that cylinder, where the operation herein described is repeated. As many of these pipes and connections, as may be considered necessary, may be used, the pulp each time passing under the mercury and being subjected to the agitating action of the steam jets, as well as to the action of the heat supplied by the introduction of fresh steam at different points.

The gauges show the hight of mercury in the cylinders at all times. The last cylinder of the series may not need any mercury and may be used to catch any particles of that metal which may be forced over with the pulp.

It will be seen that this process is continuous in its action and that no machinery is necessary for carrying the ore along through the cylinder. Steam may be supplied from the boilers which furnish steam for the crushing apparatus. The process employed is much more thorough than where amalgamation is attempted by passing the pulp over amalgamated copper plates, and is much less expensive than when the pulp is treated in pans, no loss of quicksilver being involved. When the cylinders are once filled with mercury, whatever may pass over will be caught in the succeeding ones or the last one. The manner of injecting the steam for transferring the pulp from one cylinder to the other is very effective, not only for that purpose, but for agitating and beating it as it goes through. Every particle of ore must go through the hath of mercury with no possible means of avoiding it, and the mass is so stirred and agitated during its passage that a thorough amalgamation of the precious metals is effected.

The pulp is thus agitated over and over, receiving a fresh agitation and a fresh supply of heat as it enters each cylinder. The use of the kettles or bowls saves any loss by leakage. The supplemental agitating pipe with the spray nozzle on its lower end, under the surface of the mercury, assists in overcoming one of the main objections previously urged against the plan of forcing ore under a body of mercury. When brought under the mercury, by a tube in the center of the bath, the pulp is apt to rise in lumps, the outside portions of which only are in contact with the mercury. This is caused by the weight of the metal keeping the pulp in the same shape in which it enters it. By violently agitating the mercury in the manner described and forcing the pulp into it, in a finely disseminated condition and by the addition of this supplemental agitating tube, any lumps that may have formed will be broken up and the pulp distributed evenly throughout the mass of mercury, thus allowing all the particles of precious metals in the pulp to come in contact with the mercury.

Brains in Mining.

Charles Schofield, under recent date, writes the Tnolumne *Independent* on the importance of employing brains—that is ability and judgment in the business of mining. We abbreviate his communication somewhat. During a long experience in mining, I have found, says the writer, that, while nothing can be done without labor and some capital, still I am of the opinion that four-fifths of the failures that have occurred in quartz mining in California are attributable to a scarcity of brains in the conduct of the business. The most common mistake has been that of building mills, roads, etc., before the mine was sufficiently explored to determine whether such expenditure would be warranted or not. Next has been that of going about the development of a mine in a round-about and expensive manner, involving everything in uncertainty, when a more direct and less expensive plan would have insured success. Managers lacking brains and experience, plan long tunnels and deep shafts without taking into consideration the natural dip of the vein or pitch of the chute, and having, after much expenditure failed to strike ore, come to the conclusion that the vein *don't go down;* whereupon a new management is inaugurated or the enterprise abandoned, generally the latter. Having by a number of practical examples illustrated this sort of mistake, the writer proceeds as follows.

"After citing one more instance I will, as the lawyers say, submit my case.

"A *gentleman* in San Francisco made an investment in mines, not very far from Groveland, and placed a brother in charge, whose only recommendation was the fact that he was known to be good for nothing else, and therefore upon general principles it was thought he ought to make a good mining superintendent. The consequence was that he attracted a class of men about him as ignorant and worthless as himself, and selected his boarding-master as his principal adviser, or in other words, to furnish brains for the enterprise; and as the *gentleman* last mentioned did not happen to have a very large supply of that article, besides having to divide with his Chinese cook, there was a very small amount left to be applied in furthering the business in hand. The upshot of the matter was, that where it was thought necessary to sink a shaft, they were sure to start on the wrong side of the vein; and where a drift was to be run, it was in the opposite direction from where the pay chute was known to lie; where they found themselves directly under the chute they sunk directly away from it; and without waiting to ascertain whether they had a mine or not, they built a mill for which they never had any use, as they never succeeded in finding any rock, although an abundance of rock was close by and almost in sight. The consequence of this management was that they got in debt to nearly everybody, and finally left in disgust, which was only equaled by the disgust of their creditors.

"There is also occasionally a great lack of brains among mill men. Some mills, like the Golden Gate, are loaded down with all sorts of useless traps, clogging the power and requiring two or three extra men to run it, while others scarcely have anything to save their gold, to say nothing about sulphurets, be they ever so plenty and rich. Some mill men show great tact in running their tailings into a river, creek, or some other place where the waste cannot be seen; and though they are known to be losing thousands, they keep on, unwilling to allow others to erect suitable machinery, even though they are offered one-half of all that is saved without any expense on their part.

"Then sheer stupidity sometimes works a deal of mischief, as is shown in the case of the Star Co. above Columbia, who had a small mill erected, with the best of appliances for saving sulphurets. Their sulphurets being plenty and rich it was their principal purpose to save them. Among the quartz as brought to the mill was a large percentage of slate full of thin films of mica (sulphate of iron.) This light flaky substance, having been mistaken for genuine sulphurets, the superintendent used all his energies to save it, and as it was very light and floated with the water it required no small amount of skill. He erected large tanks below the concentrator; but as these would soon get full and run over, his distress was unbounded, and although all else seemed to work well, and the mica lost, was not worth a cent per ton, its loss caused him to stop the works, and a general collapse ensued from which it is doubtful whether he will ever recover."

THE INTERNATIONAL PHYLLOXERA CONGRESS. It will be remembered that in August, 1877, an international congress of wine-growing countries was held at Lausanne, at the instance of the Swiss government, for the purpose of devising some common measure of repression and prevention of the phylloxera plague. The negotiation then set in progress have led to a joint agreement in common action between Germany, Austria, Spain, France, Italy, Portugal, and Switzerland, the ratification of which by the Swiss government is now expected. Soon we shall doubtless learn the character of the international campaign which is to be undertaken against the insect.

THERE is a surplus of gold in Omaha.

The Ethics of Journalism.

In no country on the face of the earth has the newspaper gained such an autocratic position as in the United States. One of our national prides is our freedom of the press. Whatever other powers the people have relegated to their law-makers, they seem to have refused the power to interfere with the newspaper, except in cases of gross libel, which the courts shall adjudicate. This is well enough. We do not believe that any general act can be framed for the regulation of the public prints which would not do as much evil as good; which would not abridge true freedom as well as repress license. The regulation of the press is in the hands of the people, and that is where it rightly belongs, for the press is, in a certain sense, the voice of the people, and the people can determine whether it shall be false or true. It rests with the patrons of newspapers to decide what their code of ethics shall be. From them comes the support which makes newspaper existence possible; with them lies the power to say whether this existence shall be for good or for evil.

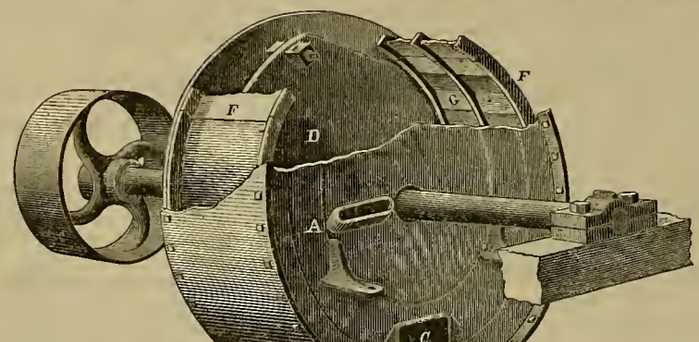
There can be no doubt in the minds of any one who reads the newspapers of the day that the public is often too lenient with the creatures of its power. Policies and motives are permitted to thrive in the conduct of newspapers which would not be tolerated in any other concern or institution existing by popular favor. And the evil is most insinuating and demoralizing. Men who would cut from their acquaintance one whom they detected in an outright falsehood, will continue to contribute money to the support of papers which they know well are given to the publication of the most shameful lies. Men who would strike to the earth any one who should carry a suspicion of shame to the purity of their households, will welcome, day after day, sheets which are reeking with polluting influences. Men who are quick to discern the rogue who would undermine their success and risk their fortunes under the guise of friendship, will still contribute to the support of papers which they plainly see are propagating the deadliest fallacies in the garb of philanthropy, or reaching for the rewards of demagogism under cover of claims for public benefit. Men who would denounce such wrongs if attempted in any other form, will quietly gulp down these sugar-coated pills of perfidy and perdition administered by the public press. And while prints, which are thus encouraged by patronage, can hold the support of the truth-lovers and at the same time serve for hire the interests of those who thrive upon the success of sinister designs, it is little wonder that we see such perversions of the freedom of the press as now exist. It is simply by the public sufferance that such things are possible. It is simply because the managers of such low-toned and truckling sheets can bag the dollars of the well-disposed but thoughtless people, and at the same time drive bargains to sell the influence which this patronage bestows to those who will pay highest for it, that we see the wonderful and disgraceful exhibitions of journalistic gymnastics.

This is not a pleasant theme, but it is one of the utmost importance. What surety of right and safety is there when the voice of the people, as spoken by the press, is permitted to sink to the approval of false ideas of public policy? Who can tell to what end of wrong the tendency may go which takes its rise in the subjection of principle to the claims of private interest. What encouragement is there to individual uprightness, truth and nobility of purpose when the public press makes yesterday's outlaw the hero of to-day? What surety of the permanence of a good name by a life of disinterested goodness, when those who were yesterday pronounced dangerous to the public safety are to-day proclaimed the people's saviors? Blinded by partisanship and led by greed for gain, journals which public patronage should make zealous custodians of the general good are transformed into cringing, truckling servitors of personal ambition and propagators of profitable falsehood.

Is there no remedy? Yes, there is a sovereign remedy so long as the majority of the people are, as they are to-day, truth-lovers, patriotic and resolute. No fire will burn without fuel, and no service of the false will succeed unless it have the support which the friends of truth afford. If any journal gives unmistakable signs of selling truth for selfish gains, cut it off. Let it lose the support of the upright, and it will fall. If a journal aims to thrive by furnishing a fund of incidents and ideas which appeal to the baser passions, and fill the mind with low and groveling thoughts, banish it from pure homes into the outer darkness which its tastes approve. There may be other approaches to the journalistic heart, but the one which is most available to the public is through the cash box. Withdraw support, and the proudest structure falls. Withdraw support, and the journal which lends its eminence to the service of evil, will either purge itself of its evil or go down with it. Thus the people may determine that no journal shall live unless its ethics be high-toned and true. Unless it labor for truth, for purity, for uprightness in individuals and in public affairs, let it be plain that the public does not approve of its existence. There is no surer way for the people to secure a press which shall be true to the trust placed in its hand. There is no more direct way to determine that the press shall be held true to its high mission, and that is, free, fearless and untrammeled maintenance of the right, and unyielding denunciation and suppression of the wrong, in whatever varied forms it may appear. The remedy is sharp and decisive: be sure that the occasion calls for it, and then apply it quickly, as one would set foot upon the reptile which invades the home. There is no deadlier foe to public safety than falsehood in the public press.

Gold in India.

Since the finding and partial re-opening of ancient gold mines in India, with some remains of the implements by which they were formerly worked, the following from a London paper relative to the recent discovery of gold-bearing quartz lodes in that country will be read with interest. According to their late report it appears that the Moyan Coffee Co. leased, last year, a portion of their property to the Prince of Wales Co. for the purpose of having it prospected. The result was that from 20 tons of quartz, 45 ounces, 6 pennyweights of gold were obtained, inducing responsible parties to apply to the company for the exclusive right to work their lodes.



THE DAVIS ORE PULVERIZER.

The board stated that they knew the company possessed a large area of reefs, and that Mr. Brough Smythe (the Minister of Mines in the government of Victoria) had been deputed to thoroughly inspect the country, and from the company's lands gold was produced in small but perfectly visible quantities. The chairman, Mr. A. Hall, congratulated the shareholders on the fact that large quantities of gold had been recently discovered on their property; and, in reply to a shareholder, who asked whether the government reserved the mineral rights of the land, Mr. Hall said that he consulted all the title deeds, and there was no reservation in that respect. He had also consulted gentlemen in the India office, and the government had not made, and were not likely to make, any claim to those rights. After some discussion with regard to suggestions as to the forming of a new company or altering the present articles of association to enable the company to deal with and develop their gold prospects, it was resolved to form a committee of gentlemen possessed of mining knowledge to thoroughly investigate the subject.

JOHN MILES who acquired notoriety at Salt Lake last fall in the Miles-Owen polygamy case, has been surrendered by his bail to the United States Marshal, and incarcerated in the penitentiary.

THE millmasters of Ashton-under-Tyne have decided to begin a general lockout on Saturday if the strike is not settled. The strikers are estimated at 10,000.

THE French Atlantic cable is broken 161 miles from St. Pierre Miquelon, in 500 fathoms of water.

The Davis Pulverizer.

We illustrate herewith the Davis ore pulverizer, a California invention, which is now being introduced to the mining public. These machines are at work in this city; at the California Portland Cement Co., at Santa Cruz; the Wasson S. M. Co., New Boston, Esmeralda county, Nevada; Angel's Landing, Carson Hill, Calaveras county; at the Gunsight mine; one at Oroville; one at Meadow Lake, etc. That at the Santa Cruz Cement Works is stated by the manager to run 3,300 pounds per hour through a No. 50 screen.

The various parts of the machine, and its mode of working, can be fully understood by referring to the illustration, where *A* represents the feed opening through which the ore is passed into the machine. *B* is the discharge spout, which can be set at any angle desired, but is found in practice to work best by being at the bottom, as represented in the cut. *D* is the disk to which the shoes are secured. *FF* are the corrugated dies around the periphery. *G* represents the face of the die; also, the annulus or ring that divides the machine, so that it may be fed from either or both sides, as desired. *E* represents the shoes attached to the disk. *C* is a hand-hole for putting on the shoes or changing them when worn.

The pulverized ore passes out by the force of air between the openings at the ends of the dies, and is discharged against the outside shell, finding its way out at *B*. When the shoes, *E*, are worn so as to require changing or turning, it is only necessary to remove the hand-hole plate at *C*, loosen the nut with a socket wrench, and replace them. The outside case is made of heavy sheet-iron, put on in sections, and secured with bolts to the projecting flanges, so that the dies can be changed or removed in a short time.

The principle upon which the machine works is that of attrition—that is, particles of ore coming in contact with each other at a high velocity—the office of the machine being to keep the ore in motion until its reduction is complete. It takes rock from the breaker, and by adjusting the outlets, which can be done in a few moments, delivers it in a continuous stream, reduced to any fineness desired. Its construction is simple. The only parts that do wear are made of cast-iron and can be readily obtained from any foundry.

Each one of these machines is claimed to equal in capacity 20 stamps; and it is also claimed that they do the work with much less power.

The machine is made of such light parts that it can be transported to any portion of the country on pack mules, and for prospecting can be made to suit any required want. They can be set up in three or four days, requiring only a few timbers as a foundation. There is but little machine work about it. All the parts that do the work are made of plain cast white iron, and can be replaced in a few moments.

There are no grinding surfaces in the machine; no points where iron comes in contact with iron. The ore is taken up by the shoes, and thrown against the corrugated disk of dies and reflected, when it is again taken up and again thrown against the disk, and this is repeated until the ore is sufficiently fine to pass out of the orifices, the discharge being produced by the impact of the atmosphere. By this device, a uniform pulverization is secured.

These machines are made by the Davis Pulverizer Co., the office of which is at rooms 9 and 10, No. 405 California street, where further information will be given if desired. The machine is of course intended only to crush dry, and is, therefore, especially adapted for gold ores. It will, however, of course crush any kind of ore, rock, etc., or, in fact, anything of a hard nature.

AN ARIZONA FIBER PLANT.—We read in the *Arizona Sentinel* of a new fiber plant (botanical name unknown) which grows wild in large quantities on the Colorado river bottom. Specimens have been shipped East and they are said to have excited great interest among the manufacturers of fine fabrics in New York and New Jersey. It is said to be in every way superior to ramie, and dresses up with a finish equal to that of the finest silk. The specimens of the fiber shown at the East, and also sent to Europe, were five and six feet long, and by their beauty, strength and length, created quite a furore among certain wealthy manufacturers. A botanist has been sent out there and is now traveling on the river gathering specimens for classification, estimating areas covered by the plant in its natural growth, and examining into the feasibility of its profitable gathering, or cultivation for commercial purposes. The Southern Pacific Railroad Company takes an active interest in this matter and is lending material assistance toward its investigation. The plant forms dense thickets on the river bottoms, growing to a hight of four to seven feet, in stalks little larger than a lead pencil. Its roots are very tough and so matted together that it takes at least two yoke of oxen to draw a plow through them.

THERE will be 13,697 feet of tunneling between Alma and Santa Cruz, on the South Pacific (narrow gauge) Coast railroad, of which 7,514 feet are completed, leaving 6,183 feet unfinished.

Railroads.

Guatemala Railroad Co.

Chronicle, Jan. 14: The ship *Reunion*, at Mission-street wharf, chartered by the Guatemala Central Railroad Co. takes a cargo of railroad supplies to the port of San Jose de Guatemala, to be used in the construction of the road extending from the latter port to the city of Escuiutla, Guatemala, 28 miles from the sea. The cargo will consist of about 1,800 tons of railroad ties, a large quantity of iron-plating and castings for building purposes, coal, rice, construction implements, and last, but not least, about 100 Chinamen, who will be put to work at once on the line of the road. Seven miles of the road-bed are already prepared for the rails, and they are on their way from New York via Panama, and will be received in San Jose about the time the *Reunion* reaches there. This enterprise, the successful inauguration of which has been quietly accomplished, cannot fail to ultimately result in great benefit to San Francisco. The present objective point of the company is Escuintla, to which city they have a franchise from the government of Guatemala for 99 years, and during the first 25 years thereof, after the opening of the line, they are guaranteed a net profit of 12% per annum on $1,000,000 and a loan of $210,000 towards construction. It is the intention of the company to eventually push the construction of the line to the city of Guatemala, almost 60 miles inland.

The city of Escuiutla is the great center of the coffee trade of Guatemala, and, when once facilities are given for moving it, the production will be greatly increased. The present annual exports from the coffee section consist of about 6,000 tons of coffee, 300 tons of cochineal, 300 tons of hides, 300 tons of rubber, cocoa, etc., 300 tone of timber and native manufactures. By far the most important of the future prospects of this road, however, is its extension to the Atlantic side, a distance of little more than 200 miles, where it reaches the magnificent harbor of Santo Thomas, the finest port between New York and Rio Janeiro. The Gnatemala route has no serious topographical difficulties to overcome, and is 2,000 miles shorter than the route via the isthmus of Panama.

Oregon and California.

The *Oreyonian* of January 25th, says: Mr. R. Koehler, agent for German capitalists interested in the O. & C. R. R. and O. C. R. R., was called some months ago to Fraukfort-on-the-Main to report to the boudholders, upon the affairs of the road. He returned by the *Oregon*, on her last trip, and he confirms a statement, that the bondholders have decided to extend the road to Corvallis, 50 miles from its present terminus. He informs us that while in New York Mr. Villard and himself contracted for steel rails, the same in pattern and weight as those on the Central Pacific road between Sacramento and San Francisco, and for all the necessary rolling stock and motive power. The rails are completed, and will be shipped for Portland immediately. Mr. Koehler has contracted for ties and has put in the field a locating party now busy in the vicinity of McMinnville. The road will go by way of Amity and Dixie. Grading will commence as soon as right of way is obtained.

Oregon Narrow-Gauge.

The *Oregonian* further publishes the following from Ellis G. Hughes, Vice-President of the road, copied from the Brownsville *Advertiser:*

Your favor of the 19th inst. making enquiries as to the use of Chinese labor in the construction of the Oregon Narrow-Gauge road is at hand. It is our purpose to do almost the entire grading of the road with plows and scrapers, and in such work only white labor can be used as a matter of course, nor do we intend to use anything else in getting out ties, laying track, etc.; however, there are some parts of the work such as heavy cuts, etc., which will probably be let by contract. When we let in this way we will let at the lowest prices attainable, and as a matter of course the contractor will employ such labor as he chooses.

The subscription at Salem is progressing favorably, and I donht not will be closed in a few days, and at Lebanon, Scio and Aumsville, and elsewhere along the line the people are alive to the importance of the road to them and are earnestly pushing forward the good work, and I have no doubt will have their part of the subscription complete in a very short time.

As we must await the completion of the subscription before ordering our material from the East, or taking any active steps in the construction of the road, it is desirable to have the entire matter closed without delay if it is desired to have the road completed this year, and if there has so far been only $10,000 subscribed for Brownsville and the surrounding country, it is necessary that it push the work with more energy if it would not he left in the race.

Santa Rosa and Napa.

The project has been revived for the construction of a railroad from Santa Rosa to some point in Napa or Solano counties. The object is to place Sonoma county generally in direct communication with the Sacramento valley and the railroad system of the State. The proposed road will also be of advantage in other ways. The North Pacific railroad will soon be extended from Cloverdale to Ukiah. This will make the projected road an outlet generally for the northern coast counties. All passenger travel and freights from Sonoma county to the northern portions of the State are now carried by water to San Francisco, and thence to the Central Pacific and California Pacific railroads. This occasions great loss of time, besides incurring considerable expense in the handling of freight. Sonoma is one of the leading counties in the State for producing early fruit; but the growers there must remain at a disadvantage, so far as Eastern markets are concerned, until there is direct communication with the trans-continental road.

The entire length of the proposed road will be 38 miles, of which the distance between the towns of Sonoma and Napa junction is 13 miles. It can be graded its whole length at an average cost of $1,500 per mile. The ties would cost, in addition, $600 per mile. Engineering and other expenses will raise the cost of the road-bed to about $125,000. The citizens of Sonoma county propose to subscribe that amount, grade the road, put the ties down, and then bond it to some Eastern manufacturing firm for supplying rails and the rolling stock.

There is still a large area of redwood forests in Sonoma county. Although they are within a comparatively short distance from the Sacramento valley, yet lumber from the mills of Sonoma for that district has to be carried between 200 and 300 miles. The projected road will open direct communication, and thus increase the facilities for putting down the lumber of Sonoma in all the counties of the Sacramento valley. Such a road as the one projected must be constructed at some time, or Sonoma county must remain isolated from the northern counties of the State.

Atchison, Topeka and Santa Fe.

According to the Silver City *Herald*, a great reduction has been made in the passenger fare on this road. This reduction took effect January 1st, 1879. To all points in Kansas rates are reduced to four cents per mile. Through rate from Trinidad to Kansas City is $28.25. One thousand mile tickets will be sold for $30. No second-class or shipper's ticket will be sold. Also, freight tariffs have been greatly reduced, and hills of lading will he made by agents of the A. T. & S. F. to all points on the D. & R. G.

South Pacific Coast Narrow Gauge.

A correspondent of the Santa Cruz *Sentinel* writes as follows: This railroad is being constructed in a solid and substantial manner, the ties and iron being of extra thickness. A railroad man of much experience says that it will he one of the best and safest roads in the United States—that is, for a narrow-gauge. The road will probably not stop at Santa Cruz, but be run on south. Branch lines will probably be run in through Hihu's Angmentation, and it is probable that a line will be run from Felton to the Great Basin. The camp at the south end of Tunnel No. 6, presents an animated appearance; 450 Chinamen and 50 white men are encamped in the canyon. A white man has started a saloon, and a Chinaman, a store and opium den. The Chinamen employed by the contractors are all hired from two companies in San Francisco, and are little better than slaves. They receive nothing directly from the men for whom they work—all the money is paid to the company, which pays them when the contract is completed.

In Nevada.

The Gold Hill *News* of Jan. 21st, thus discourses: D. O. Mills, the chief owner of the Virginia & Truckee railroad, has returned from his Eastern trip. It is generally understood that his mission East was to buy railroad iron and rolling stock for the proposed railroad from the Mound house to Bodie. The contract to cut 250,000 ties was made last September, and they are ready now. In a year the road will be running to the new camp, and in two, it will be pressed through to Los Angeles, and give us another route to California. It will be of the same gauge as the V. & T.

Clinton Narrow-Gauge Railroad.

The San Francisco *Bulletin*, of January 24th, has the following: This is a private enterprise seldom spoken of, yet of considerable magnitude. It is used for logging purposes, and is four miles in length, tapping the heavy belt of timber near Lake Tahoe. At the terminus of the road there is a chute 1,700 feet long, into which the logs are dumped. Down this chute they fly and fall into the river. Once there it is an easy matter to take the logs to the mills. The workmen, taking advantage of the hardness of the ground, are bringing from 60,000 to 70,000 logs daily, to he taken down in the spring. The road has one locomotive of seven tons weight, and six flat cars. The cars can convey 100,000 logs daily to the head of the chute. There is talk of pushing the road through to Lake Tahoe

---

To Make Iron Take a Bright Polish Like Steel.—Pulverize and dissolve the following articles in one quart hot water: Blue vitriol, one oz.; borax, one oz.; prussiate of potash, one oz.; charcoal, one oz.; salt, one-half pint; then add one gallon linseed oil, mix well, bring your iron or steel to the proper heat and cool in the solution. It is said the manufacturers of the Judson governor paid $100 for this recipe, the object being to case-harden iron so that it would take a bright polish like steel.

A great deal of difficulty is experienced in cementing metal to glass. The *Faerber Zeitung* says that a mixture of two parts finely ground litharge and one part white lead, and working it up to a stiff paste with three parts boiled oil and one part copal varnish, adding more litharge and white lead as required, is the best material for joining the two substances.

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,
North Bloomfield, Nevada Co., Cal., October 1st, 1878.

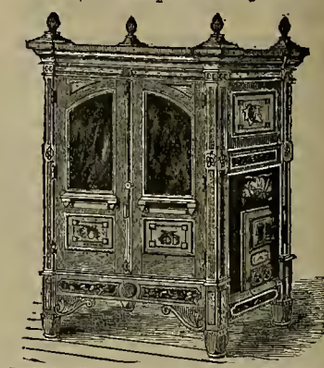
Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Gegroet, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

DEFLECTED HEAT!

Boswell's Combined Heater, Cooker, Baker, Clothes and Fruit Drier.



Combining the advantages of a Stove, Furnace, Oven, Dry House and Kitchen Range. An application of Scientific Principles to the economy of living, of labor, of health and of comfort. A handsome piece of Furniture adapted to the wants of every family. It equally economizes time, labor and fuel, and avoids exposure to heat in cooking as well as in baking. It bakes Bread, Cakes and Pies to any desired tint without turning or watching, or danger of burning. All odors produced in cooking are passed up the flue. Food cooked by deflected heat is improved in flavor, more easily digested, contains more nutriment, will keep fresh longer, and is also much improved in appearance. The stages of the cooking or baking can be seen without stooping or opening the doors of the oven. It will dry and bleach your clothes in from half an hour to one hour and a half, and heat your irons.

Fruit dried in the Boswell will gain from TWENTY to FORTY PER CENT. in WEIGHT, and THIRTY PER CENT. in QUALITY over that dried by any other process. It will successfully dry any kind of Fruit, Grapes, Berries, Meats, Fish, Vegetables, Coffee, Tobacco, Corn and Grain of all kinds.

— ALSO —

Boswell's Commercial Fruit Drier,

Used exclusively for drying and heating purposes ON A LARGE SCALE.

— ALSO —

BOSWELL'S CABINET HEATER,

Of all sizes and capacity for heating Private Residences, Hotels, Halls, School Houses, Churches, Offices, Stores, Railroad Cars, Hospitals, etc.

All of which can be operated successfully by a mere child, it is so simple in its construction, and with one-third the usual amount of fuel (coal or wood), used in any other heating, cooking or drying apparatus.

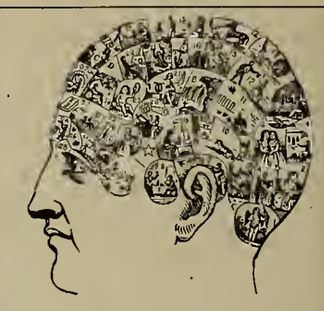
Every farmer and economical housekeeper should use it. It will pay for itself in the saving of fuel; it will pay in the superior character of its FRUIT DRYING, of its COOKING, ROASTING and BAKING; it will pay in its salubrious and healthful warm air; it will pay the rich and the poor alike.

Address, for Price List and descriptive illustrated circulars,

Boswell Pure Air Heater Co.,

No. 606 Montgomery Street, San Francisco, California.

S. R. LIPPINCOTT, Secretary.
EUGENE L. SULLIVAN, Pres't.



Barlow J. Smith. M. D.

Consulting Physician,

Professor of Phrenology and Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenological Institute, 635 California Street, above Kearny.

This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervous derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-motorpathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermal, Russo-Turkish and Medicated Baths given daily.

Mrs. Dr. Smith as Matron has charge of the female bathing department.

Dr. Smith has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiognomy, in examining or diagnosing disease in this city, and claims to have made discoveries in the Science of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness; whether Consumptive, Dyspeptic, Rheumatic, Apoplectic, Neuralgic, Leucorrhœal, or Seminal. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds.

Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Power and Wells' charts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph.

Phrenological or Physiognomical examinations without charts, $1.50; with charts, from $2 to $3.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 8 P. M. Sundays from 9 A. M. to 12 M.

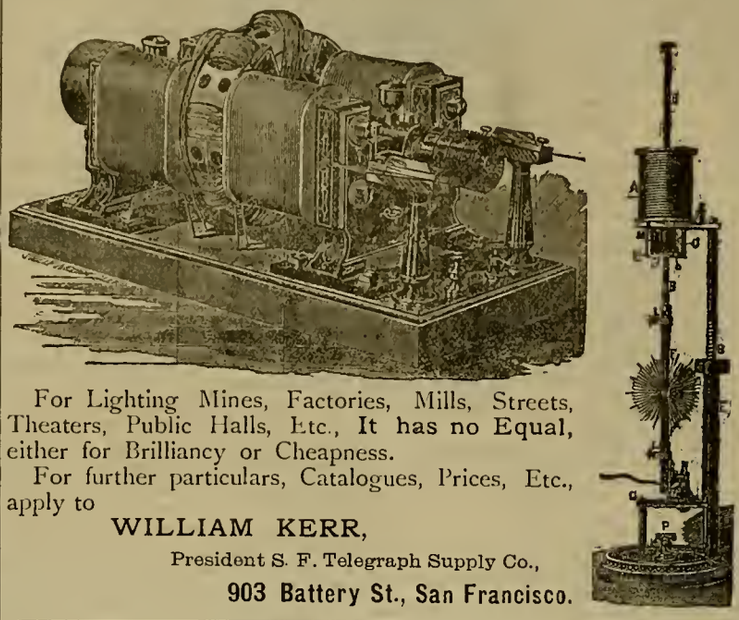
ELECTRIC LIGHT.

BRUSH PATENT.

The Best, Cheapest, Cleanest, and Most Powerful Light in the World

In daily use at the Palace Hotel and the Union Iron Works, S. F.



For Lighting Mines, Factories, Mills, Streets, Theaters, Public Halls, Etc., **It has no Equal,** either for Brilliancy or Cheapness.

For further particulars, Catalogues, Prices, Etc., apply to

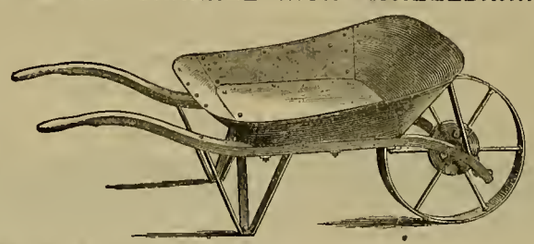
WILLIAM KERR,
President S. F. Telegraph Supply Co.,
903 Battery St., San Francisco.

FRANCIS SMITH & CO.,

MANUFACTURERS OF

THE PATENT CHANNEL IRON WHEELBARROWS,

SHEET **IRON PIPE.**



IRON PIPE. SHEET

The Strongest Barrow Made. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe Also, Galvanized Iron Boilers, from Twenty-five to One Hundred Gallons.

Iron Cut, Punched, and Formed for making pipe on ground, where required. All kinds of tools supplied for making pipe. Estimates given when required. Are prepared for coating all size of pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 BEALE STREET, San Francisco, Cal.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED COPPER AMALGAMATING PLATES.

The BEST PROCESS yet discovered for SAVING FINE GOLD. Extensively used in Mines and Quartz Mills. Over FIVE HUNDRED ORDERS have been filled for these Plates.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco.

E. G. DENNISTON, - - - - - - - - - PROPRIETOR.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature, thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

HEMORRHOIDS OR PILES,

A treatise on their scientific treatment and radical cure, by E. J. FRAZER, M. D., San Francisco. Price, 25 cents; for sale at the bookstores and by the author at 221 Powell street. Sent by mail to any address on receipt of the price in coin, currency or postagestamps.

Picturesque Arizona.

By E. CONKLIN, Representative of the National Associated Press, and artist and correspondent of Frank Leslie's publications. Being the result of Travels and Observations in Arizona during the fall and winter of 1877. Fully illustrated. Sent by mail, post paid, for $2.00. Address, DEWEY & CO., 202 Sansome Street, S. F.

507 Mechanical Movements.

Every mechanic Should have a copy of Brown's 507 Mechanical Movements, illustrated and described. Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, $1, (post paid.

[Continued from page 133.]

very smoothly on Jackson ore, mixed with other ores, smelting daily 35 to 36 tons. Ore is being delivered from the Williams, Adams Hill, Dunderberg, Bullwhacker and other mines.

MAJOR MCCOY is working eight men in the Grant, and taking out some rich silver and lead ore. No mine in the district gives brighter promise of a rich yield.

PARTIES from Tem Pahute say that the Wyandotte company's ledge is eight feet wide in ore of a high grade. Twenty-eight men are employed, and no more are needed. The company has labored under many disadvantages, especially in regard to water, which they are gradually overcoming. They propose to bring water a distance of 80 miles. The company's bills are paid regularly every month.

PARADISE DISTRICT.

PARADISE VALLEY.—*Silver State*, Feb. 24: At north drift below tunnel No. 1 the ledge is considerably mixed with slate in the upper part of the drift. The slate is crowding down on the ledge. Bottom of drift nearly all in quartz. Tunnel No. 2 will soon be under this drift and below the break. A fine ledge of high grade ore is exposed in the Bray cut. No work is being done at this point. Work on tunnel No. 2 is being pushed ahead, and will soon strike the ore body, which will lessen the cost of extracting. In the fifth level and open cut a fine body of ore is being opened up. The ledge on the fourth drift, which has been small and of a low grade, is improving very rapidly, both in size of ledge and quality of ore. From present indications we shall soon open up a fine body of ore in this part of the mine. In tunnel No. 5 work is progressing very slowly, as but one shift is being worked. This work is being done by contract. The mine is extracting and shipping daily about 10 tons of ore to the Rye Patch mill; also taking out a quantity of low grade ore, which will pay to mill when the company erects a mill.

WHITE PINE DISTRICT.

THE BALDY SOUR COMPANY.—Eureka *Sentinel*, Feb. 16: Col. Robinson has ordered work commenced on the Baldy Sour and Sweetwater mines. On the former, which has 100 feet of tunnel completed, a contract has been let to drift north. A contract has also been let to sink a shaft on the Sweetwater mine. The indications on these two mines are very encouraging. Col. E. N. Robinson is President of the Baldy Sour company, and left for New York several days ago, where he will perfect his financial arrangements, and return to White Pine in a couple of months.

REESE RIVER DISTRICT.

WESTERN NYE.—Grantsville *Sun*, Feb. 17: The Alexander mine is yielding richer ore than ever, and new discoveries and rich developments are constantly being made. The mill has been running uninterruptedly during the past week, and is doing splendid work. The company have shipped $9,000 in bullion.

BELMONT DISTRICT.

BELMONT.—*Courier*, Feb. 22: The mine is looking fully as well as at any time, and the stopes yielding their usual amount of rich ore. Have advanced 300 level drift 11 feet during the past week in hard-blasting ground; are at present running in the footwall, but expect to be in ledge again by the end of the coming week. The vein in this level has been very irregular its entire distance from the shaft, and to avoid making sharp curves in a working drift, they are compelled, at times, to go in foot or hanging wall. Have advanced south raise, north end of mine, 15½ feet in a good, strong vein of quartz, which is three feet thick to-day at face, showing some nice bunches of ore all through it, but is not rich enough to pay for saving yet. Number of tons assorted ore for the week, 12; average assay, $106.

HIGHBRIDGE.—During the week the usual amount of work has been done in the different ore stopes with good results. On the lower level they have advanced the drift north 25 feet; total distance from shaft, 50 feet. South drift advanced 32 feet; total, 47 feet.

GILA.—During the past week the crosscut was advanced 18 feet, with little change in material. In cutting out for the station, 164 feet below this crosscut, they discovered a promising streak of vein matter. They are in on it now a distance of 20 feet, with very encouraging prospects. It will be followed until some change takes place, when sinking will be resumed in the winze, which cannot be done at present with their limited hoisting facilities; the rock being soft in both places, either one of which will keep the windlass constantly employed. The south drift winze shows no change.

ARIZONA.

GLOBE DISTRICT.—*Silver Belt*, Feb. 21: There is a continued improvement in the quality of the quartz found in the Metamora shaft, now in 160 feet. We hear good accounts from the mines at Gold Hill and Lost Gulch sections. They hold out well when sunk upon. A new discovery has just been made of a very large lode, carrying both gold and silver. There is a prospect of the Miami mill getting a liberal support from this region at an early day. At the end of a 21-foot drift, in the 120-foot shaft of the Silver Queen, property of L. G. Crane, the ledge has been struck showing leaf silver. The Alice shaft is down 95 feet and a streak of 18 inches of good ore is found in the bottom. There is some nice ore on the dump. Fifteen miners at work on the McCormick mine. New discovery in the tunnel of Stonewall Jackson is rich, and promises to be extensive. The Washington lode, formerly known as the Aiken, promises well. The Hannibal Mining Co. has let a contract to run a drift in good ore. Work is to be resumed on the Champion mine.

PATAGONIA DISTRICT.—*Sentinel*, Feb. 23: The murder of Messrs. Finlay and Adams caused the suspension of operations, though the mine was then making a splendid showing. The ore vein is of great size and fair grade, and magnificent bodies of metal have already been exposed. The mine lies in a thickly wooded and grassy country; close to the cheap labor and cheap supplies of the Santa Cruz valley; and within little over 247 miles of the seaport of Guaymas, over an excellent natural road now about to be used for the new Guaymas railroad.

PAPAGO MINING DISTRICT.—*Star*, Feb. 20: The shaft on the Alleghany is down 30 feet with rich chlorides at the bottom. Shaft is five feet wide and all in ore, and the width of the vein has not yet been ascertained as it is much wider than the shaft. The ore assays from $75 to $100 in silver. On the Pittsburg there are three shafts, the one now being opened is down eight feet, going down on the foot wall, and has three feet of metal. This ore averages from $50 to $150 per ton in silver. The San Juan has two tunnels, the first on south end of the lead is in 137 feet. There is a shaft on the lead in the tunnel 20 feet deep and the metal at the bottom of this shaft is 14 inches wide. The tunnel on the north end is 47 feet. Shaft upon the lead in this tunnel is 18 feet deep and has eight inches of rich ore and a large body of average rock. Several experts have examined this mine and made assays which average $100 to the ton.

UTAH.

BINGHAM.—Cor. Salt Lake *Tribune*, Feb. 23: The amount of ore in the Bulldozer in deposit is difficult to estimate. A drift of 280 feet has been run entirely in gold-bearing ore, free milling and bearing no lead. At the outset the footwall was struck, since which time the drift has been run entirely in ore. Free gold is frequently met with, and the pan produces colors in every wash. As this mine is in close proximity to the Stewart, upon the same hill and the same character of ore, there is no doubt that it will rank as high as any in the canyon. A recent strike in Barney gulch is attracting attention. The location was made last December, consequently not much work has been done. It is named the Greenborn. An incline has been run on the vein about 20 feet, and several holes sunk to trace the vein, which has been found to extend over 500 feet. Assays made from various portions of the vein run from $11 to $40 gold, carrying but little silver and no lead. The Saturn is turning out some fine galena ore. It is now under lease to Klopenstein & Co. The Moscow and Centennial are working on ore. The Bully Boy has been leased to Ben Kennedy and McCourt for a period of nine months. Mr. Duignan is working the Silver Hill with tolerable prospects. The Ashland is being worked under lease by Jackson, Trinneman & Co. They are making a shipment of about 25 tons of good ore.

MINING NOTES.—Silver Reef *Miner*, Feb. 15: A rich strike is reported to have been made in the Compton mine, adjoining the Duffin mine. The ore was struck in the tunnel at a distance of 150 feet, showing a body of about four feet of ore. The sinking on the Stormont mine goes regularly on at the rate of about two feet every 24 hours. The vein of ore is six feet thick, three feet of which is high-grade ore. When an additional depth of 50 feet is attained, stoping of the ore will be commenced. Pahria and Jackson have become synonymous words for fraud, humbug, and bilk.

News in Brief.

MAJOR RENO is not to be court-martialed.

SANTA ROSA had an earthquake on the 19th.

ANOTHER revolution has broken out in Hayti.

A STRIKE has occured in two cotton mills at St. Petersburg.

THERE are no flowers in Stanislaus county this month, as usual.

A NEW YORKER has started to ride on horseback to Patagonia.

A RISE in the Loire is causing disastrous inundations at Nantes.

GEN. SHERMAN will leave the East April 1st for the Pacific coast.

THE police put a stop to the female boxing match in the city.

ENGLISH hams are preferred to American in the Brazilian market.

ELECTRIC lights are being introduced into business houses in the city.

IN Big Cottonwood Canyon, Utah, there were 13 snow slides on the 10th.

THE police have so far made 164 arrests in this city the present month.

NEW YORK Custom House officials are collecting duties on smuggled dogs.

Two hunters were murdered by Indians near Deadwood on the 20th inst.

HALIFAX is blockaded by snow. The drifts in some places are 20 feet deep.

THE United States frigate *Constitution* has been towed into Lisbon disabled.

THE British steamer *Zanzibar* from New York to Glasgow is reported lost.

A NEW vein of coal has been discovered in North Park Colorado 18 feet thick.

GRAND DUKE NICHOLAS of Russia has been banished for publishing a pamphlet.

THE Atchinson, Topeka and Santa Fe railroad is completed to Otero, New Mexico.

ANOTHER expedition has been fitted out to search for the Walker Honduras treasure.

THE *Victoria*, the first ironclad vessel built on this coast was launched on the 22d ult.

ARREARS in pensions up to the passage of the Pension Arrears act, aggregate $34,000,000.

A POPULAR Mexican editor has been murdered at the instigation of a high government official.

AMADOR COUNTY contains 428,000 acres, of which only about 20,000 are under cultivation.

CAPT. PAUL BOYNTON has started to float from Pittsburg to New Orleans in his life-saving suit.

MANY people are building floating houses along the Sacramento river in preference to dry land lots.

THE War Department has ordered ten of the new Hotchkiss mounted field guns for use on the frontier.

BOSTON has sent out 600 kegs of horse shoes for the use of London, Liverpool and Cork omnibus horses.

UP to the present writing there have been issued 32 whisky licenses in the new town of Otero, New Mexico.

IT is said that a sufficient quantity of cocoons was raised in Utah county, U. T., last season, to make 500 yards of silk.

AN ocean steamer, 1,200 feet long, of 100,000 horse power and able to sail 23 miles an hour, is being built in the East.

THE business men of Bodie talk of organizing a protective association against the numerous deadheats of that section.

LIEUT. FLETCHER who so disgracefully eloped with Miss Bailey of Baltimore, has been found and will be court-marshaled.

A TEN-year-old boy in New York killed his grandmother in a fit of passion and was sentenced to 30 days' imprisonment.

AMONG 205 doctors recently graduated from the University of the City of New York, the second on the list is a Chinaman.

THE surface of Tulare lake is now about 18 feet below the high water mark of 1862. The greatest depth about 20 feet.

THE Comstockers have ceased pumping water into the Sutro tunnel, and negotiations are to be resumed with a view to a compromise.

THE dead-lock in the House concerning the proposition for the repeal of Federal Election laws is likely to be of long continuance.

SEWARD, American Minister to China, refuses to produce certain official books in his possession, on the ground that they will criminate him.

AN early rupture is predicted between Gambetta and his republican followers, in consequence of the severe discipline in the Chamber.

SEVERAL horses in the vicinity of Sublimity, Oregon, are sick from the effects of an epidemic now going through that region. No case has as yet proved fatal.

A SAFE and commodious harbor has been discovered on the coast of Oregon, a few miles north of Cape Foulweather. The entrance is estimated to be 1,000 feet wide and 50 feet deep.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington. D. C.

FOR THE WEEK ENDING FEBRUARY 18TH, 1879.

IMPROVEMENT IN FLAVORING COMPOUNDS FOR TOBACCO.—D. Sternberg, S. F.

TOBACCO-CUTTING MACHINES.—L. Bauer & J. Seitz, S. F.

RAILROAD CROSSINGS.—W. B. Bernard, Sacramento, Cal., and J. D. Perkins, Elyria, Ohio.

BILL FILES. -E. H. Owen, Los Angeles, Cal.

SEWER TRAPS.—J. P. Cahill, Oakland, Cal.

——The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

ORE WASHER.—Constant Duhem, San Francisco. This is an improved ore washer and amalgamator, which we described somewhat in detail a short time since, when one of the machines was made at the Pacific Iron Works for shipment to the Gila river dry placers. The improvement consists in mounting above a suitable tank a double, perforated conical cylinder, arranged to rotate, and having internal screw-shaped flanges to carry the material through to the discharge end. The fine material and precious metals, which fall through the perforations of the cylinder, drop on to enclosed amalgamated plates attached to a cradle in the tank, said cradle being given an oscillating or rocking motion by means of a toothed wheel on the cylinder. There is also a peculiar trap or adjustable screen on the cylinder designed to catch nuggets, and under it is placed, on the cylinder cradle, a settling apron for separating coarse gold from the gravel. The *debris* or tailings in the tank are discharged by an ejector which carries them up over the edge of the tank and out of a discharge pipe.

MOUNTING RIFLE SIGHTS.—Chas. Slotterbeck, Lakeport, Lake Co., Cal. This invention relates to a novel method of mounting telescopic sights upon breech-loading rifles, so that the telescope will not interfere with the action of the breech mechanism or the loading of the gun, nor displace or interfere with the ordinary sight. In the ordinary method of attaching a telescope to a rifle, it is mounted over the center of the barrel, and thus displaces the ordinary open or globe sight. It also extends so far back over the small of the stock, that it is totally inapplicable to breech-loading rifles of many description, and inconvenient upon any. This invention consists in the employment of a device by which the telescope can be accurately mounted without interfering with the ordinary sights, and at the same time be intirely out of the way of the breech mechanism.

ROAD AND FIELD LOCOMOTIVE.—Holbrook & Pooler, Half Moon Bay, San Mateo Co. This invention relates to an improved road and field locomotive and traction engine for drawing agricultural implements or loaded wagons over fields or roads, and the improvements consist in a novel construction and arrangement of the legs, feet and operating parts in that class of traction engines in which a number of feet are employed to push the machine along, and in a peculiar method of operating these feet, so that the whole force of the engine is expended in producing tractive force and not wasted in lifting the machine at some point of its stroke.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

ANY person receiving this paper after giving an order to stop it, may know that such order has failed to reach us, so that the paper is continued inadvertently, and they are earnestly requested to send written notice direct to us. We aim to stop the paper promptly when it is ordered discontinued.

M. D. SHRADER is now an authorized agent of the PACIFIC RURAL PRESS, also MINING AND SCIENTIFIC PRESS, to solicit subscriptions and receive the money for the same. His receipts given for such money will be duly honored by this company.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

Mining and Scientific Press Patent Agency.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system and intimate acquaintance with the subjects of inventions in our new community. All worthy inventions patented through our Agency will have the benefit of a description or an illustration and explanation in the MINING AND SCIENTIFIC PRESS or the PACIFIC RURAL PRESS. We transact every branch of Patent business, and obtain Patents in all civilized countries. The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obtained through our Agency. The files of cases and official records in our office, our patent law and scientific library (already the largest west of the Mississippi), are constantly increasing. These facilities, with the accumulation of information of special importance to our home inventors, by the experience of its proprietors in an extensive and long continued personal practice, gives them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

DEWEY & CO.,
Patent Solicitors,
No. 202 Sansome St., S. F.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Office Wide Awake Prospecting and Mining Company.—No. 232 Sutter Street, San Francisco, Cal., February 1st, 1879. Location of works, Picket-Post, Pinal County, Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the first day of February, 1879, an assessment (No. 6) of four cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 2, No. 232 Sutter Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fifth day of April, 1879, to pay the delinquent assessment, together with the cost of advertising and the expenses of sale. By order of the Board of Directors. C. HILDEBRANDT, Secretary.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the fourth day of February, A. D., 1879, an assessment (No. 7) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the eleventh (11th) day of March, A. D., 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Tuesday, the eighth day of April, A. D., 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

R. N. VAN BRUNT, Secretary.
Office, Room 6, No. 318 Pine Street San Francisco, Cal.

To Consumers of High Explosives.

A card of the Vulcan Powder Company, published in yesterday's papers, requires notice from us, as the General Agents for the sale of Giant Powder on this Coast.

The Vulcan Company assert that miners obtain from them better Powder for less money than from this Company. The real fact is, that while they sell their Powder a few cents under our prices, their respective grades have always been very much inferior in strength and quality to the regular Giant Powder. This fact has been recognized by miners generally and has been shown to demonstration by careful tests, repeated from time to time with the most exact testing instruments, and in the presence of Mine Owners and Superintendents. The accuracy of these tests is beyond dispute. They have always shown so large a percentage of strength in Giant over Vulcan Powder, as to demonstrate that GIANT POWDER HAS INVARIABLY BEEN THE CHEAPER POWDER OF THE TWO.

So much for the flourish about benefiting the miners.

We will briefly notice what the Vulcan Card contains about the Giant Powder Company's Patent litigation. It says that a suit commenced in New York against Vulcan, in 1875, was withdrawn. True; that case was dismissed simply and entirely because it afterwards proved to be erroneous in form. As soon as the injunction was issued against the Vulcan by the U. S. Circuit Court of Massachusetts, (December, 1877,) preparations were made to commence proceedings in New York for obtaining a similar injunction there, but those proceedings were suspended, on account of the voluntary and summary closing up and abandoning the Vulcan Works, in New York, by the proprietor.

The Vulcan Company find it exceedingly easy, at this stage of affairs, to say they make Powder under this, that or any other patent; but on that particular point they may hereafter find that the Courts will have something to say entirely at variance with their ideas. However, the Giant Powder Company does not propose to try its Patent cases in the newspapers. It has now given to all parties distinct public notice as to its patent claims and rights, and for the present will there leave the matter.

BANDMANN, NEILSEN & CO.,
General Agents Giant Powder Company.

MINING LAWS AND DECISIONS.

Copp's Hand Book of Mining Laws.

In this little work is given the United States Mining Laws and Instructions. Also, a digest of the decisions under the laws, by the Secretary of the Interior and Commissioner of the General Land Office.

Forms are given for making out notice of location, proof of labor, application for survey, and in fact all the blanks a miner needs.

There is also a list of all the mines for which U. S. Patents have been obtained from July, 1866, to August, 1877, with location, township and range.

A handy companion for miners. Price $1, post paid Address

DEWEY & CO.,
202 Sansome Street, S. F

The "California Legal Record."

The ONLY WEEKLY containing all the decisions of the Supreme Court of California.

(The ONLY COMPLETE continuation of the S. F. *Law Journal*.)

Published every Saturday, in 8 vo. size—like the California Reports—contains EVERY DECISION of the Supreme Court, as fast as rendered, with a syllabus and statement of facts, and other important legal matter. The volumes commence on the first of October and April each, and have a full index for reference and binding.

REDUCED PRICE, only $5.50 per year, or $3 per volume of six months. Remit by Postal Order or Registered Letter, specifying what date or number to commence. Back numbers furnished. Sample numbers sent free. Address,

F. A. SCOFIELD & CO., Publishers and Prop's
No. 603 Washington street, San Francisco, Cal.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 202 Sansome St., room 7.

FOR SALE.—16-horse Engine 8-inch by 16-inch bore, with 20-horse boiler. Hot water pump. Everything necessary to set it to running. Price, $1,000. At Jackson's Agricultural Machine Works, S. E. corner 6th and Bluxome Sts., San Francisco.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,
Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

THE SAFETY POWDER COMPANY,

San Francisco, Cal.

CARTRIDGE.

GEN. W. S. ROSECRANS, President.

COL. SAM'L O. GREGORY, Secretary.

Fuse Lighter and Fuse.

Safety Cap and Fuse.

Electric Cap.

Safety Powder, Caps, Electric Caps, and Fuse Lighters.

Under a series of U. S. Patents, after long and carefully conducted experiments and thousands of tests, this Company is prepared to manufacture and supply, for Mining and Engineering Works, the above named articles at prices and on terms as favorable as articles of similar grades are now supplied in this market. Our Powders contain no Nitro-glycerine, no Nitroline, no Gun Cotton, no Fulminates, and are free from the unavoidable dangers in manufacturing, transporting, handling and using of all high grade explosives which contain those elements.

Cold does not affect them. They cause no headaches or other inconveniences in handling, and the smoke from their explosion contains no poisoning or sickening vapors.

Their blasting force, with slight tamping, at least equals that of any Powders now used, but they admit and require strong tamping to bring out their immense and peculiar lifting power which follows their detonating work. They should be fired, therefore, by our

"Safety Cap,"

Which allows tamping without danger. They can be fired by any caps now employed in blasting, but the use of these is always dangerous with any Powder, and the loss of the throwing power resulting from lack of tamping renders it with our Powders doubly objectionable.

Our SAFETY CAPS have twice or thrice the force of triple Giant Caps. When set on fire they do not explode, but merely burn off, and are perfectly safe in transporting and in tamping.

In round tin boxes, 50 cents.

The Safety Fuse Lighter,

Cheap, handy and sure to light the Fuse upon the end of which it is fastened, only needs a trial to be appreciated by every miner who is up to "snuffs." 25 Cents per box; sent by mail.

Safety Fuse,

Equal to the best in the market, will be supplied at the lowest market prices.

SAN FRANCISCO, SATURDAY, MARCH 8, 1879.

VOLUME XXXVIII Number 10.

Boiler Explosions—No. 1.

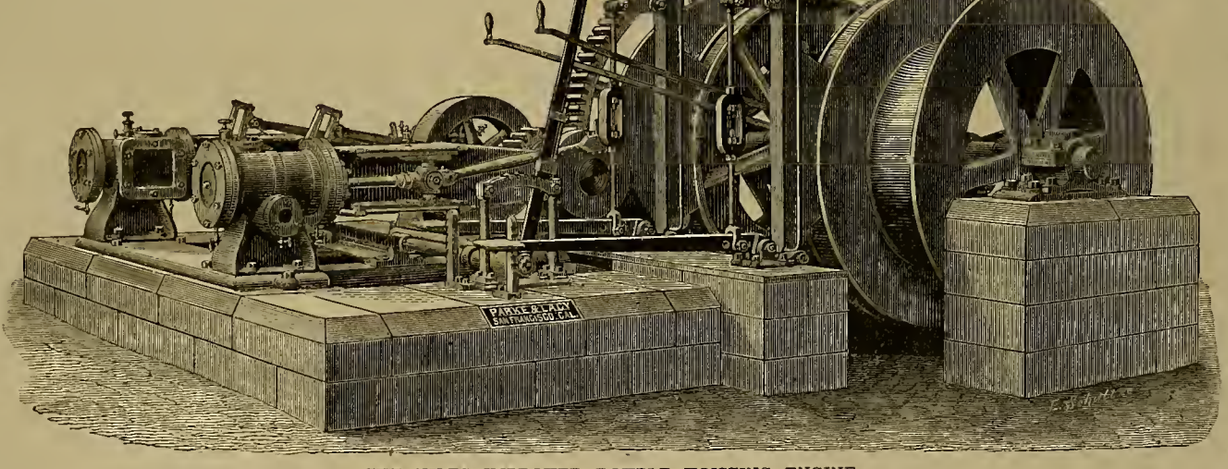
[Written for the PRESS by H. W. RICK.]

The exploding of portable and threshing engines is becoming of such frequent occurrence that people have just cause for fear at the manner these useful machines are handled by incompetent persons, as well as by those who are pronounced to be good engineers, but who have not made themselves masters of all the minute details which it is necessary to thoroughly understand. Very many of our best engineers and machinists who go out into the harvest fields to run threshing engines cannot repair a steam gauge, and when one is taken apart would not even know if it were out of order. The bursting of the boiler in Stockton, which caused such terrible results, could have been prevented by having had a new steam gauge on the boiler at the small cost of five dollars. The driver or engineer who had charge of this machine was considered to be one worthy of his calling. He had considerable experience both in the field and in the shop, but he may never have seen the inside of a steam gauge; at least he did not know that when the pointer of his gauge indicated only forty pounds that there was probably from two to three hundred pounds pressure upon his boilers. This explosion was not more terrific than others which have taken place near Stockton, and in other parts of the State within the last few years. A greater number of persons were killed from the fact that there were a greater number collected together, and it so happened that the heaviest part of the machine was thrown to where the greatest number were standing. This boiler was made of good material, the work of putting it together was well and strongly done, and it was capable of standing a pressure much greater than would ever be required to do any work which the engine was able to perform. It is apparent that it was exploded from great pressure, as the sheet, which is the under part of the furnace gave way, that being the weakest part of the boiler. This was an arched or crown sheet about two and one-half feet square. It did not collapse or cripple down as would be supposed but detached itself entirely from the parts which were held by stay-bolts, and was blown out of the furnace in the opposite direction from that taken by the heavier parts.

The part consisting of the boiler, engine flywheel, trucks, etc., was thrown to a distance of 100 or 150 feet, and the mass must have weighed, when it started, at least 6,000 pounds. It was shot through the air as a rocket is propelled, and is an illustration of what an immense power there is in steam when it is brought to such a fearful pressure. There is not a doubt but there was plenty of water in the boiler at the time, and that the boiler was clean and in good order. The safety valve beam was fastened down by a coil spring balance which did not have an index or register, and there was no way to ascertain by it that there was any extra heavy pressure. This is to say the least, a poor contrivance, and should never be used on any boiler.

While it is not wise to hold the engineer blameless, it is much more dangerous to believe what so many of the knowing ones say, when they tell us that they would have done this thing or that thing, and that they knew it all the time, etc. For instance, on the second day, after the accident, while standing near the place talking with engineers and eye-witnesses, an individual stepped forward and in a very excited manner said: "I stood right along side of her. I was looking right at her. I saw the sides of the boiler going in and pressing out, etc," How many times has this been said before by firemen or helpers around engines, and when will men cease to be so wise and skillful that they cannot learn anything?

One person made the remark that boys 14 years of age were allowed to run engines, and blamed the carelessness of engine owners. It may be remarked that it is much easier to keep boys from running engines, than it is to enlighten men who have arrived at the ripe age of 30 or 40 years, and are so wise that they would not learn of a boy, if the boy happened to know a great deal more than they do. There is a class of unskilled men who having been fireman or watermen for a short time only, will, for the sole purpose of getting a few dollars extra pay, recommend themselves, and, although they get through the season without accidents, it may be attributed to good luck rather than any knowledge which they possess. There are books and publications which are easily obtained at very small expense; besides, if a man wishes to become familiar with an engine, he could, by spending a little time, take one apart and put it together again, and even should he pay a competent mechanic to give him instructions, it would be much better than to be speedily sent to eternity, taking along so many others who are quite as unprepared and unwilling to go. We shall have more to say on this subject in another article.



THE NILES IMPROVED DOUBLE HOISTING ENGINE.

The Niles Double Hoisting Engine.

We illustrate herewith one of the Niles improved hoisting engines, designed specially for use on this coast, by Messrs. Parke & Lacy, agents. Several styles of this hoist are made, double with single drum, single with double drum, etc. The illustration represents one of the double engines with double drum, a very powerful and compact machine. They are in use at the Eureka Consolidated mine, Eureka, Nevada, the Guadalupe quicksilver mine, Raymond & Ely, Price & Davis, Hoosac, and other mines on the coast. The spur wheel and reels are made in sections, so they can be taken down small shafts and set up underground. All the gears are cut, which is a decided advantage. Some of the hoists of this style are now being built in sections, no piece weighing over 300 pounds, to be packed on mule back into the interior of Mexico.

The End of a Swindler.

Philip Arnold, one of the promoters of the successful diamond swindle perpetrated upon certain New York and San Francisco capitalists some six years ago, died recently at his home in Elizabethtown, Ky. We say successful, if the consummation of a scheme so nefarious can in any sense be called a success. Of Slack, his aider and abettor in this business, we have heard but little since he escaped with his share of the loot from this to the other side of the continent. Being a person of less shrewdness and thrift than his confederate in crime, he failed to invest his money wisely and, in fact, we believe soon lost the most of it, after which he subsided into his original obscurity. Arnold, however, having employed his capital to better purpose, had managed it seems to not only largely increase his original stock, but also succeeded in making himself quite popular in the neighborhood where he took up his abode. Being a banker and able to extend financial accommodations to the needy, and practicing an unbounded hospitality to all, his plausible version of the diamond affair was accepted by the people amongst whom he lived without much scrutiny; being generally regarded as a smart trick practiced upon a set of knaves who would have played the same on him had opportunity offered.

And so, Philip Arnold was held in tolerable repute in his old home; built himself a fine house, bought a farm and improved it highly; kept a stud of fast horses, and prospered in a way that seemed likely to falsify the old adage of honesty being the best policy, and other aphorisms of similar purport. But it didn't quite turn out that way in the end: our banker having gotten into a difficulty with a rival doing business in the same town, the trouble lead to a personal squabble that culminated in a shooting scrape, in which Arnold, after killing an innocent man with a shot aimed at his antagonist, was himself so badly hurt that he died from the effects of the wound soon after—died while yet a comparatively young man—died before he had hardly more than tasted the fruits of his ill-gotten gains; his reputation blasted and his memory burdened with that basest of all crimes, ingratitude to benefactors and perfidy to friends. It was a poor exchange, after all, that Philip Arnold made—this of bartering away the ever-conscious sense of integrity and a not dishonorable poverty, for an infamously acquired wealth.

However the inhabitants of this little Kentucky village, accepting his account of the affair as correct, might feel disposed to condone his offence, there is here, where the matter is better understood, but one opinion in regard to it; this community being quite unanimous in the belief that Messrs. Arnold and Slack were guilty of perpetrating a contemptable piece of villainy, for which they richly deserved to be sent to the State prison; and that they escaped expiating their crime by a long term of penal servitude, was simply because the men whom they had inveigled into this miserable business did not care to have their good names still more besmirched through a further connection with it.

This diamond swindle was not merely an immoral, but was in every aspect of the case a highly criminal procedure. It was even marked by such a disregard of pledged faith and the claims of friendship, as to many honorable minds is more abhorrent than crime itself. The parties to whose influence and exertions this scheme was mainly indebted for the small measure of success that attended it, were themselves grossly deceived and misled by the miscreats who originally planned it. Coming from the same section of the South and holding like social and political views with Arnold and Slack, they reposed the greatest confidence in their integrity and believed all they said. Hence the mischief, both they and such of their friends as they had induced to embark in the enterprise suffering heavy pecuniary loss and exposing themselves to the suspicion of being the authors and promoters of the fraud. Ignorant and unknown Arnold and his accomplice could, unaided by men of position and means, never have floated their scheme upon the public. The improbability of their pretended discovery would, but for the well known and reputable names of these parties, have invited such close scrutiny, as must have exploded the thing at the start. The expert sent to examine the "find" was thrown off his guard, and committed a blunder into which he would not otherwise have fallen.

Although they captured and got away with a considerable amount of money, the fate that seems to have overtaken this brace of rascals is not calculated to encourage to a numerous following in their footsteps; the one having been speedily dispossessed of his plunder, while the other, after enjoying his dishonest gains for a season, stains his hands with additional crimes and dies as the fool dieth, leaving some property and an unsavory reputation behind him. Of a truth the ancient but homely saying that "what comes over the devil's back is sure to go under his belly," seems in the case of these two men to have been amply verified.

METEOROLOGICAL SUMMARY FOR FEBRUARY.—The report of the United States Signal Service officer, of San Francisco, for the month of February is summarized as follows: The mean hight of barometer for the month was 30.126; mean temperature, 54.1; mean humidity, 79.2; prevailing winds, west; highest barometer, 30.420; lowest, 29.797; highest temperature, 70°; lowest, 43.5°; monthly range, 26.5°; greatest velocity of wind, 29 miles per hour; total number of miles traveled by wind, 4,471; total rainfall, 4.90 inches. Rainfall in February during former years: 1872, 6.90 inches: 1873, 3.94 inches; 1874, 2.21 inches; 1875, .32 inches; 1876, 4.92 inches; 1877, 1.18 inches; 1878, 12.52 inches.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Letter from Arizona.

Pioneer District—Slow Movements and their Causes.

EDITORS PRESS:—Although silver ore was discovered in this district several years ago, not until the past 18 months was anything effectual accomplished towards working the mines; and even the amount of exploration yet done is inconsiderable, in view of the encouraging surface indications met with in various parts of the district. It is only about eight months since there have been any facilities here for the reduction of custom ores, these facilities being still limited and inadequate to the requirements of the country. This slow progress has been caused not so much from a want of merit in the mines as by the peculiar customs that prevail among prospectors and other extraneous conditions,

The High Prices of Freights

Being one of the greatest obstacles to the mineral development and general advancement of the country. With the exception of breadstuffs, which are raised abundantly in the Gila and Salt River valleys, everything consumed here is brought from San Francisco, the average cost of through freight, having heretofore been eight cents per pound, and the time 40 days, is now diminished somewhat by the carrying forward of the railroad up the Gila. With this tax, which falls heavily on mining machinery in particular, it requires considerable capital and faith in the country to inaugurate operations of any magnitude. The present showing of the mines, however, would seem to warrant the requisite outlay, and two small mills, to be devoted chiefly to custom work, having been brought in here last summer, give prospectors and mines a chance to realize something at once. In the event of the completion of the Southern Pacific railroad as far as Maricopa Wells, the freight would be reduced nearly one-half, and the time to about 12 days.

"This Country Needs Capital."

Ever since the discovery of the precious metals, in this part of the Territory, the above has been the loud and incessant cry of claim-holders. Locations that could have been made to pay their own way from the beginning, have been permitted to lie idle while the owners exhausted their time and means in hunting for capital. The time was when men located mines for the purpose of working them on their merits, the strong and willing hand of the miner rarely failing then to wrest its reward from the wealth they contained; but times have changed, and with them men also. The spirit of speculation is rife among all classes, and the honest miner has not escaped its blight. He no longer looks upon his mine as the legitimate means of making money by the sweat of his brow, but as a thing created for the express purpose of being sold, and the "lucky miner" is now the one who gets the highest price for the poorest claim. This mania for selling mines gave rise to the countless fables of untold wealth found here on every hillside. These reports were persisted in and industriously circulated to attract the attention of capitalists, whose money was not so sorely needed for the development of the mines as to pay the big prices set upon them. The effect was to bring here a great influx of men of various classes. Many of them were indeed capitalists or their agents searching for investments, and these, for the most part, finding nothing approaching what they had been led to expect, condemned the whole thing without stopping long enough to learn the true value of the country.

The demand for "capitalists" was so great that every person arriving was sought out and interviewed the moment he reached any mining district; almost as soon as he entered the Territory. It was hard for the stranger to resist the temptation to assume the character of an Astor for an hour, thus thrust upon him, and many amusing incidents grew out of this tendency to cast a halo of millions around any beggar who might turn up. Even newspaper correspondents were sometimes through mistake wined and dined and whiskyed, and offered "the richest mine in the Territory" for a paltry hundred thousand. So many sharps at length began to assume the role of the capitalist that the business fell into disrepute, the proprietors of the hotels and bars having especially reason to remember these Arizona capitalists with loathing disgust, and to speak of them profanely.

Could the sale of mines have been effected as contemplated by the locator, the district would have gone ahead swimmingly. But they seemed to have lost sight of the fact that the same foresight and care that enable a man to accumulate money also prevents him from dishursing it for less than its equivalent. A location that might change hands among prospectors for the consideration of a sack of flour or a broken six-shooter, would be blandly offered to a moneyed man at $15,000 or $20,000, while claims having any silver in sight and a good vein cropping out would be held much higher. If a reasonable reduction of 98% were asked, the owner might be induced to lower the price one-half, he falsely arguing that a wealthy man could afford to pay any price for it. Here negotiations usually ended, wherefore comparatively few sales have been made, and those usually where the owners have been forced by circumstances to accept reasonable prices. To develop the mines of this district, would require but a comparatively small amount of capital—to purchase them would strain the resources of the Rothschilds. No great degree of prosperity can be looked for until the locators of these mines either go to work on them themselves or consent to terms which will enable others to do so.

Need for Some Further Congressional Legislation.

The only law recognized here in locating and holding claims is the Congressional act of 1872. This was no doubt passed and approved under the impression that the miners of the various districts would frame and adopt such further restrictive laws as circumstances might require. The mining lands being as much a part of the public domain as any other, they should be as jealously guarded against the wiles of the speculator and grabber. The law is very strict in regard to the amount of agricultural land which one person can locate and hold, the location of a second claim implying the desertion of the first. But it is silent in regard to the number of mining claims which one person can hold, the custom being, and the courts maintaining, that it is without limit. This is repugnant not only to the spirit of our government, but to common sense and justice, for it enables a few men who happen to come early into a mining region to lock up the treasures of a whole district and levy a sort of tribute or blackmail on those who come later. Nor is this the only defective feature of the law. It allows one year in which to perform $100 worth of work on a claim, or virtually gives a man the privilege of holding any amount of mining land for a whole year without making any improvements on it whatever, while the custom, which is to place the most liberal construction on the law, only aggravates the matter, by holding that if a man be on the ground with tools at the time the year expires, he may go on with the work and hold the claim for the second year. The loose customs which prevail here are, in fact, a great injury to the country and somewhat in conflict with the law. It is not considered necessary to mark the boundary of a location, as the law provides. Two or three small monuments with a single notice indicating the general directions of the lines are supposed to be enough, so that many claims are made lapping on each other. The clause which presumes that a mineral-bearing vein shall be discovered before it is claimed, is also entirely ignored, the rule being to claim the ground and take the chance of finding something on it afterward. The requirements of the law in this particular are very generally dodged. It is no uncommon thing for several prospectors, or more properly speaking speculators, holding a dozen claims, each to preconcert arrangements whereby they relocate each for the other when the time for doing the assessment work expires, the ground being afterward deeded back, and the law cheated of its rights for another year.

These loose ways, in general, are not only causing present trouble, but they are sowing the seeds of endless future litigation. Even now it is hardly safe to make a discovery of any value unless one is ready to defend it at law or by physical force. Now if Congress is going to legislate upon the subject at all, it should do so effectively. Miners, as a class, are averse to much law, and having a general one are loth to frame local codes, fearing conflicts and complications. Several attempts to organize district laws here have been defeated by the mistaken assertion that "the United States law is good enough."

If the benefit of the people at large is the object of law, it would seem that a stringent act of Congress properly enforced and correcting these and other flagrant abuses would meet the case. After reviewing all these obstacles which the district has had to contend against, enough it would seem to blight the progress of the most favored land, the wonder is that anything at all has been accomplished toward the legitimate operation of the mines. The outlook for the future, however, is at present better than ever before. There is a noticeable tendency on the part of miners to give up the delusive hope of selling out at fabulous prices and get down to the actual business of working their mines for the ore they will yield. And the want of capital, though there is room for more, is not so badly felt, now that there are milling facilities enough, at least, to keep the wolf from the door. ASSAYER.

Arizona, Feb. 18th, 1879.

Galvanizing Steam Boilers.

EDITORS PRESS:—I desire to call your attention to a suggested improvement, that, if properly carried out, might be of much public value. It is the galvanizing of steam boilers. I investigated the matter a few years since, and thinking it would be a great protection, in case of using salt or mineral waters (nearly always found in mining districts), made application for letters patent, which were refused on the ground of lack of novelty. The new application to steam boilers was the foundation of my claim.

I should like that some person would put this suggestion in practice and give it a fair test.

A. D. ROCK.

Eureka, Nev., Feb. 28th, 1879.

Old Fort Miller and Surroundings.

EDITORS PRESS:—The business travels of your correspondent in this region, have brought him to what was once an important point of the Upper San Joaquin river, where it begins its exit from the foothills of the Sierra Nevada mountains. I allude to the old Government station, known as Fort Miller, which was established in 1851, on the south bank of the stream. Blake, in his instructive and valuable work known as "The Geological Reconnoisance of California, etc.," prepared as one of the reports of Lieut. Williamson's expedition in 1853, gives a full description and a handsome engraving of the cove and surrounding mountains at this interesting point on one of California's two chief rivers. Judge Charles A. Hart, an old and respected citizen of Fresno county, owns the former

Site and Buildings

Of Fort Miller, and has there a valuable ranch and garden. As his home, he occupies with his family one of several well-constructed adobe buildings, which remain standing in an excellent state of preservation. There is not perhaps on this coast a finer sample of an adobe building than Judge Hart's. Its walls are about 30 inches thick, and it remains almost entirely unmarked by the earthquakes and storms through which it has passed during the last quarter of a century. The Judge took me through his garden, which, on the 7th of December, was in full cultivation: Chinese mustard, tomatoes, peppers, lettuce and other vegetables growing in luxuriance, still unnipped by the slightest frost. Yet heavy frosts had prevailed for more than a month throughout the San Joaquin valley westward of the foothills, and at a less elevation above the sea than is this cosy, picturesque nook, but a few miles above the broad, level plains. This fact known, your readers will not wonder that orange, lemon, almond, and fig trees, and choice grapevines, to say nothing of other fruit and nut trees, are growing most rankly and thriftily. Here the common red pepper is growing perennially, plants of it blooming and bearing year after year. For garden and orchard, irrigation is received from a spring, more than a mile distant, in the higher foothills.

This instance proves that

A Valuable Fruit Belt

Exists along the foothills of the Sierras in these southern counties, where frost is almost unknown, as is proved at Newcastle and other points for the corresponding parts of Sacramento valley. To utilize this truth, in Merced, Fresno, Tulare and Kern counties, only irrigation, industry and moderate means are requisite.

The site of old Fort Washington is found on the fine ranch of V. B. Cobb, seven or eight miles below Fort Miller, on quite a long stretch of bottom land, occupied by the valuable farms of the Birkhead Bros., W. J. McNeill, William Witt, Col. Lane, and others.

Half a mile below Fort Miller is the little that remains of Millerton—once the county seat of Fresno. The substantial brick Courthouse, with its jail basement of granite, remains standing, and is used as a school-house. But two white families live in this truly deserted village, the rest being given up to the numerous Chinamen, who are mining considerably along this part of the river, and for 30 miles above.

Two miles below Millerton, about half a mile below Converse's and Jones' old ferries—no longer kept up—is to be the head-gate of the

Upper San Joaquin Irrigation Canal Co.'s Canal,

To which allusion has already been made in your columns. Their camp has already been formed and work begun. Your readers will be farther informed of its future progress. This company which controls some 80,000 acres—to be irrigated eventually by this canal—offer a rare chance to industrious men of moderate means to work upon the ditch with their teams, be paid in company's stock, and afterwards if they wish, buy land and water rights for this script, which will be taken at its par value in payment for such land. This enterprise is affording a present home market for surplus hay and barley.

I must tell your readers of the most extensive and best sustained mining enterprise that has yet been attempted upon the gold-bearing gravel of the San Joaquin river.

In January, 1877, the

Kentucky Mining Co

Began the constuction of a mining ditch 14 miles long. It is now completed, with three miles of flumes. It also furnishes water for two other mines, along the San Joaquin and its tributaries, known as the Frieze and the Fine-Gold mines. Messrs. Hampton, Donahoo, Howard and Holt are among the chief stockholders, the former being Secretary, and Mr. E. F. Holt, Superintendent. Their ditch, as I am informed, runs from 250 to 300 inches of water—miners' measure—the supply never failing. Their method of work is entirely the hydraulic. Their works have cost up to this time $10,000 or $12,000.

Having spent some 18 months in the completion of their ditch, they began work about a month ago, and are well pleased with results. Their claim extends two miles along the river front, their present work being just opposite old Fort Miller. Their gravel varies in depth from 10 to 30 feet. They find considerable blue gravel, but most of it is granite, partaking of the nature of the vast masses of rock here and for many miles up the river. Mr. Holt assures me that they find this to be a first-class gold-bearing gravel deposit. He informs me that the mining enterprise in Fine-Gold gulch is also doing well, as are other mining projects in this district. You and your readers will be pleased to learn, that the mining as well as the farming interests of Fresno county are looking up—and surely these twin sisters of California's industry should always go hand in hand, if they do have family quarrels once in awhile.

J. W. A. W.

Fresno Co., Cal., Dec. 9th.

From the Comstock.

EDITORS PRESS:—The east shaft now being sunk in the Sierra Nevada mine from the 1700 to the 2200 level will, it is expected, be completed within a week. If the ore found farther south in that mine extends as far north as this shaft, the fact will most likely then be demonstrated. It may be, however, that the ore, though it extend that far north, will not be intersected by this shaft, in which case a crosscut will have to be run west from the bottom of the shaft to reach it. Should the ore be found to reach to this point, it will tend to show that it is a body of considerable dimensions, the distance thence south to the incline where ore is known to exist being about 500 feet. It is also known that ore extends from the 2100 level at the incline to the 2300 level, and presumably farther down. How far it extends south from the incline is not known.

Awaiting results of farther exploration there is much anxiety manifested among all classes. Meantime, gambling in the shares of this mine goes on actively, and should anything occur to send up the price of this stock, it will no doubt take up others in the immediate neighborhood with it. There is much need of bonanza developments here, as the old ones are being worked out. There are anticipations of important changes to take place in several of our mines for the better, and it is to be hoped that such will prove to be the case, as we stand in great need of a greater output of ore. The influence would be felt far and wide. The many mills that are standing still would be started up, and hundreds of idle mechanics and miners get employment, effecting a most desirable change in the affairs of this sage-brush community.

Several important connections have been made between shafts of different mines at quite a depth lately, much improving their ventilation, and more are about to be made, which will facilitate working in the lower levels, thereby affording opportunity to extend explorations in virgin ground, with good hope that ore may be found.

J. D.

Virginia City, Nevada, Feb. 25th, 1879.

M. TREUVELOT, a foreign scientific observer, has been experimenting with butterflies, in order to solve the disputed question as to the use of the antennæ. He found they could fly when deprived of the antennæ, but with some hesitation of movement. When blinded they did not perceive sugar by the antennæ; but if the stump were touched with it, the proboscis was at once unrolled and searched for it. M. Treuvelot concludes that the sense located in the antennæ is not merely that of touch, hearing or taste, nor a combination of all three.

A GOOD oil for gun-locks, etc., is said to be made in this way: Fill a phial three parts with almond oil, then fill up the remainder with clean lead chips. Keep the phial in a warm room and shake it now and then for a month, at the end of which time most of the mucilage and acid naturally in the oil will have combined with the lead, and thus be clarified and fit for lubricating gun-locks, reels and other similar work.

A NOVELTY IN FIREARMS.—A Spaniard, of Madrid, has invented a novelty in revolving firearms. It consists in the addition of a special chamber for receiving from the rear end of the cylinder, a portion of the gas resulting from the explosion of the cartridge, and conveying it to one of the discharged chambers to expel the empty shell.

THE State Engineer party, under Major Warfield, is now engaged in running levels in each direction, north, east, south and west, from Visalia, in order to ascertain the fall of the country. They are also collecting information in regard to ditches, amount of land irrigated, etc.

OCEAN TELEGRAPHY.—The application of the duplex system to several of the Atlantic cables, it is said, has effected an increase in their working capacity of fully 70%.

LAST year 3,606,465 cigars and 5,500 cigarettes were made in Maine, consuming 89,814 pounds of tobacco, while $20,832 worth of revenue stamps were used.

IN sinking a well 60 feet deep at Blackfoot, Snake river, gold was found every foot of the way down.

MECHANICAL PROGRESS.

Steam Engines to be Superseded.

When we reflect upon the enormous impulse given to civilization by the steam engine, the genius which has exhausted every resource to perfect it, its universal use, and the grandeur and subtlety of the physical laws upon which its usefulness depends, it is almost with a feeling of regret that we listen to the prediction of its becoming a thing of the past, to be read of by future generations as only one of the steps in a long chain of sequences by which the human mind has gradually become master of natural forces. Yet the man who of all men may claim the ability to forecast the future of the steam engine, whose eminent ability has been directed through a long and industrious life almost wholly to the investigation of the principles of steam power, thus prophesies.

We refer to Mr. John Bourne, in whose greatest, and perhaps final work, entitled "Steam, Air and Gas Engines," he uses the following remarkable language as part of the opening chapter:

"The present time is one of movement and apparently of impending revolution in the means of obtaining motive power. The steam engine having for nearly a century been the only efficient thermo-dynamic motor, and after having remained without any change in its principle or action, and even without any striking improvement in its details since it was dismissed from the hands of Watt, is now, I believe, on the eve of supercession by simpler and more economical machines. And, although among a host of competing contrivances, we cannot yet single out any one to which we should be warranted in doing homage as the prime move of the future, and although each an engine has probably yet to be invented, still there is no reason to doubt that it will before very long appear.

"The number and variety of the schemes which have been put forward for obtaining motive power from heat show very clearly the existence of a wide-spread perception of the enormous faults of the present steam engine, and of the exigent need which exists for the introduction of some better contrivance to take its place. To the creation of this sentiment I believe that I myself have in some measure contributed. In the first portion of my "Treatise on the Steam-Engine," published in 1844, I intimated the conviction that the steam engine would pass away; and in subsequent editions of that work, and also in other works, I have pointed out the radical defects of the steam engine as a thermo-dynamic motor, and have indicated the direction in which improvement must flow to obtain results of practical value. The great impulse, however, to the present movement for the supercession of the steam engine has been given by the discoveries of Mr. Joule, who, by a number of admirably-conducted experiments, has established the doctrine that a definite quantity of heat is the proper equivalent of a definite quantity of mechanical power; and as in the best engines it was found that not more than one-tenth of the power due to the heat was obtained, the inference was inevitable that the steam engine was a most wasteful machine, and ought to be superseded by some engine wherein the sources of loss did not exist."—*Scientific News.*

Grinding and Polishing Metal Surfaces by Hand.

There is no job the worker in metal is called on to do that requires the exercise of his brain and muscle in the proper direction than the grinding and polishing of metal surfaces on that class of work where machinery cannot aid him. The more he exercises his brain the more saving he will be of both his time and muscle. The practice generally employed by machinists in grinding and polishing either new or old work, was to mix the polishing material with oil, usually refuse machinery oil; in most cases this is a great mistake, and has caused the loss of time, patience and money. Take for instance the grinding to a true bearing of a stop-cock, a valve, seat, or a slide-valve.

There are a few machinists but what have had more or less of that class of work to do, particularly in jobbing shops, and we seldom find one who uses the same method of accomplishing the job that is practiced in shops where that class of work is made a specialty. In fitting and grinding in the plug into the barrel of a cock a little judgment and care will save a great deal of hard labor, and in no case should oil be mixed with any of the grinding material, for the following reasons: If fine emery, ground glass or sand are used with oil, it requires but a few turns of the plug in the barrel to break up the grains of the grinding material into very fine particles; the metal surfaces also grind off; the fine particles of metal mixing in with the grinding material and oil, making a thick paste of the mass. At this stage it is impossible to grind or bring the metal surfaces to a bearing, as the gluey paste keeps the metal apart; if more grinding stuff is applied it will prevent the operator from seeing what part of the barrel and plug bears the hardest. Again, if the grinding material be distributed over the whole surface, the parts that do not bear will grind off as fast as the parts that touch hard, as the particles work freely between the surfaces; should the barrel and plug bear equal all over, when fitted, it requires more care than if it were a top or bottom bearing, as that part of the barrel and plug across the "waterway" grinds twice as fast as the other parts; therefore it should be kept the driest. Now this objection holds good in the grinding of valve seats or slide valves, to wit: the separation of the surfaces of the metal by a thick, pasty grinding material. In order to bring the surfaces to a perfect bearing rapidly and with little labor, the following directions will be found worth a trial:

To grind a stop-cock of any kind first see that the plug fits the barrel, before it is taken from the lathe. Run a half-round smooth file up and down the barrel to break any rings that may be in it; a few rubs of a smooth file back and forth over the plug will break any rings or tool marks on it. Wipe both parts clean. Use for grinding material fine nicolder's sand sifted through a fine sieve. Mix with *water* in a cup, and apply a small quantity to the parts that bear the hardest. Turn rapidly, pressing gently every few turns; if the work is large and the lathe is used, run slow; press and pull back rapidly to prevent sticking and ringing; apply grinding sand and water until a bearing shows on another part; then use no more new sand, but spread the old that has worked out over the whole surface. Turn rapidly, pressing gently while turning; withdraw the plug and wipe part of the dirt off and rub on the place a little brown soap; moisten with water and press the surfaces together with all the force at hand, turning at the same time. Remove the plug and wipe both parts clean; next try the condition of the bearing by pressing the dry surfaces together with great force. If the parts have been kept together closely while grinding, and the plug has not rubbed against the lower part of the barrel, the surfaces will be found bright all over, and a perfect bearing obtained. If an iron barrel and brass plug are used, or two kinds of brass, a hard and soft metal, soap should be used freely when finishing up, as the tendency to form ringe is greater when two different metals are used.

In grinding a slide-valve which has been in use until hollow places have worn in the surface, emery mixed with water, or sand and water, will be found better than oil, unless a light body, such as kerosene, is used. If water is used with the grinding material soap should be rubbed on the hollow places, and the grinding stuff should be applied to the high parts in small quantities, keeping the low parts clean and dry until an even surface is obtained all over; then the worn-out stuff should be used for finishing up. In polishing metal, oil that will "gum up" should not be used with the polishing material, unless for a dead fine polish. In polishing old brass work which has been scratched and tarnished by wear, pumice-stone or bath brick should be used with soap and water for scouring off with, and rotten stone with kerosene for the wet finish, and dry for the final polish. The same method should be used for new brass work.

New work should require, when leaving the lathe and vise tools, but little polishing or grinding, and every good workman should try to avoid using an emery stick or emery cloth, for with proper care in the use of tools a great deal of grinding and polishing can be dispensed with.—*American Machinist.*

Paper bricks are the latest novelty. A manufactory of such bricks has recently been established in Wisconsin. The bricks are said to be exceedingly durable and moisture-proof. They are also larger than the clay article. Paper is now also used for making barrels. Straw pulp is run into a mold made in the shape of a half-barrel, cut vertically. The ends are of paper, but are protected by wood. The barrels are lighter and two-thirds cheaper than those of wood, and flour will not sift out of them while in transit. The staves are three-eighths of an inch thick.

Bessemer Steel Anchors.—It is stated that the British Admiralty have decided to adopt the use of anchors made of Bessemer steel, which can be had at less than one-half of the price paid for the costly "best" iron hitherto used; but it yet remains to be seen how far the quality will be the same. This extension of the area in which Bessemer steel is now used is likely to be of great value to the steelmakers, if the experiment prove successful, and to have important effects on the chain and anchor trades.

Mechanical Giants.—We recently made some notice of the construction of an 80-ton gun. The success attendant upon that enormous piece of ordnance, has encouraged the attempt to produce a 160-ton gun. As a necessity for such construction a lathe of enormous dimensions is now being built at the Woolwich arsenal. Another of the coming mechanical giants is a 1,000-ton revolving crane. There appears to be no limit, but cost, to the magnitude of mechanical constructions.

Metallic Packings.—J. Strieder, of Elberfeld, uses tubes of lead or some soft metallic alloy, filled with hemp, cotton or some other suitable vegetable material. These tubes can be prepared of great length and cut to fit any given requirement. The ends may be either soldered together or forced into close contact. The convenience, durability and cheapness of this packing are especial recommendations.—*Dingler's Pol. Jour.*

SCIENTIFIC PROGRESS.

Motion by Permanent Magnets.

When a large, very thin iron disk is placed horizontally, and made very easily movable upon a vertical axis passing through its center, it can be made to revolve by placing the opposite poles of magnets near its circumference, or by embracing it between the poles of a horseshoe magnet. All that is required is to heat the disk by a spirit-lamp at a point just beyond one of the poles; the rise of temperature will then diminish the attractive force of the magnet at this part of the disk, and this part consequently will turn from the magnet, its diminished attraction being overcome by the stronger attraction of the magnet on the cooler portion of the disk. When the diagonally opposite part is heated at the same time and in the same way, the motion is more rapid. It is evident that this motion can only be slow, as the varying parts of the disk can only be slowly warmed and cooled. This alternate warming and cooling could be promoted by placing pieces of ice under the disk, between the lamps and the pole toward which the disk is moving, the ice extending to the next pole, so as to keep the part to be attracted as cool as possible.

It will be seen that this motion is based on the principle that magnetic attraction is influenced by temperature, in such a way that it decreases by heat and increases by cold. It is well known that iron at about 1,000° entirely loses its property of being attracted by a magnet. Nickle loses it at 450°, and manganese at the common temperature, so that if cooled artificially it will be attracted. It is, therefore, likely that a plate of nickle would be better than one of iron, as it does not take as much heat to diminish its magnetism as it does that of iron. If, however, this advantage would not be counterbalanced by the fact that iron is attracted with more force than nickle, it is a question to be settled by experiment.

Ocean Currents.—Prof. Zoppritz, of Giessen, has investigated mathematically the question whether ocean currents are produced by the winds. One of the main objections urged against the theory that ocean currents are due to the impulse of the winds is that the winds can, it is alleged, produce only a surface drift, whereas many of the currents extend to great depths. Mr. James Croll, a high authority on this and kindred subjects, has always maintained that this objection is erroneous; that if the surface of the ocean be impelled forward with a constant velocity by the wind or by any other cause whatever, the layer immediately below will be dragged along with a constant velocity somewhat less. The layer underneath this second layer will in turn be also dragged along with a velocity less than the one above it. The same will take place in regard to each successive layer, the velocity of each being somewhat less than the one immediately above it, and greater than the one below it. In this manner the surface velocity may be transmitted downward to any depth. This conclusion has now been demonstrated by Prof. Zoppritz to be correct. The surface velocity is propagated downward, however, with extreme slowness. Thus it is found that for a mean depth of 4,000 metere it would require 100,000 years for the trade-winds to produce the existing equatorial currents.

Electro-Chemical Action Under Pressure. From a long series of experiments on electro-chemical action under pressure, varying from 100, 200 to 300 atmospheres and upward, M. Bouvet arrives at the following among other facts: The decomposition of water by a current is independent of pressure. The quantity of electricity necessary to decompose a given weight of water is sensibly the same, whatever the pressure. Oxygen and hydrogen, whatever the pressure, are liberated with equal facility. Whether they are produced in one test tube or in two, there are no secondary phenomena causing decomposition, even partial, as has been believed hitherto. When united in one test tube, even at a considerable pressure, and though forming a detonant mixture, they do not offer any danger in handling.

Hermann Herwig has extended his observations with a view of obtaining a nearer approximation to molecular distances in fluids. He concludes that no two molecular layers in water can be more than 1.86 of a millionth of a millimeter apart, and that the same is true with regard to the mean distances of adjacent molecular centers. Sir William Thompson had previously estimated the least value of the same distances at .05 millionths of a millimeter. The differences are thus as one to 37, which is probably as near as either of the figures to truth.

Darkness of Caverns.—The fact that the light of torches does not diffuse itself in a cavern is ascribed to the presence of a moldiness which covers their roofs and sides, and absorbs all those floating particles of dust which would otherwise act as reflectors.—*Les Mondes.*

Chemical Constitution of Wool.—P. Schutzenberger has published analyses of various samples of wool, from which he deduces the chemical formula $C_{230}H_{381}N_{70}O_{77}S_6$.—*Comptes Rendus.*

American Dinosaurs.—On the flanks of the Rocky mountains a narrow belt can be traced for several hundred miles, which is always marked by the bones of gigantic dinosaurs. The strata consist mainly of estuary deposits of shale and sandstone, and the horizon is clearly upper jurassic; the dinosaurian remains in this series of strata are mostly of enormous size, and indicate the largest land animals hitherto known. One new species (*Atlantosaurus immanis*) must have been at least 80 feet in length, and several others nearly equaled it in bulk. With these monsters occur the most diminutive dinosaurs yet found, one (*Nanosaurus*) not being larger than a cat. Some of these new forms differ so widely from typical dinosauria that Prof. Marsh has established a new sub-order to receive them, called *Sauropida*, from the general character of the feet. They are the least specialized forms of the order, and in some of their characters show such an approach to the mesozoic crocodilee as to suggest a common ancestry at no very remote period. In them the front and hind limbs are nearly equal in size; the feet are plantigrade, with five toes on each foot. The carpal and tarsal bones are distinct; the precandal vertebræ contain large, apparently pneumatic cavities; the sacral vertebræ do not exceed four, and each supports its own transverse process. The pubic bones unite in front by a ventral symphysis; the limb bones are solid. One of the species described and partly figured in Prof. Marsh's paper, in the *American Journal of Science and Arts*, for November, is called *Morosaurus grandis;* when alive it was about 40 feet in length; it walked on all four legs, was probably very sluggish in its movements, and had a brain proportionately smaller than any known vertebrate.

Electric Induction.—At a late meeting of the Royal Institution, Mr. J. E. H. Gordon, of the British Association, delivered a lecture on "Electric Induction," in which he remarked: As induction is not something merely passing through insulators, but has its seat in their particles, we might expect that different bodies would have different capacities for transmitting it, or, as it was called, would have different specific inductive capacities. Faraday was the first man who proved that this was the case, and who succeeded in measuring the ratios which the specific inductive capacities of various substances have to that of air, which is taken as unity. Having exhibited Faraday's apparatus, the lecturer pointed out the importance of accurate measurements, for it was only by a comparison of the electrical properties of bodies with their other physical properties that we could ever hope to arrive at the true theory of electricity. Mr. Gordon then stated that under Prof Clark Maxwell's advice, he had for three years been engaged on measurements of the specific inductive capacities of various substances. His new apparatus was exhibited in action on the table, and the specific inductive capacity of glass was determined before the audience. One important feature of the method was that, in order to avoid any permanent charging of the glass, the electrification was reversed 12,000 times per second. This was the first time that the new apparatus had been exhibited in London. As some parts of the machines were very minute, photographs of them were thrown on the screen by the electric light. A table of the results obtained was exhibited.

Minute Causes which Affect Explosions. A curious instance of the minute causes which sometimes affect explosions was given recently by St. Claire Deville, as observed by Prof. Abel. About .2 grain of chloride of nitrogen is placed in a watch glass and exploded with a piece of phosphorus; the noise is tremendous, but the explosion has little or no shattering effect. Now repeat the same experiment, after having breathed on the chloride so as to deposit a thin envelope of moisture (which cannot be more than a thousandth of a millimeter thick). In this case the explosion is less noisy, but the effects are quite different. Not only is the glass pulverized, but the table supporting it is perforated.

Nitrous Oxide Under Pressure.—P. Bert finds that by placing a patient in an apparatus where the pressure can be increased to two atmospheres, nitrous oxide can be administered so as to produce continued anæsthesis, while the blood receives its normal supply of oxygen and the normal conditions of respiration are maintained. From various experiments on animals, he thinks that gas administered in this way will be harmless, however much the insensibility may be prolonged.—*Comptes Rendus.*

Experiments with Aneroid Barometers.—The Giffard captive balloon, at Paris, was made to subserve some most interesting and useful scientific purposes during the French expedition. Among other things, it showed that all or nearly all the aneroid barometers, after registering the ascent, failed to record the difference in altitude until some time after they had been returned to the earth.

A New Variety of Coal.—The owners of the Dovenbury colliery, near Dearham, in the north of England, report the discovery of what appears to be a new variety of coal. It can be easily lighted with a candle, and burns with amazing rapidity and clearness, leaving behind scarcely any ash. They were offered a very high price for this coal for gas making.

Mining Share Market.

The past week has becu rather a stupid one, and interesting events connected with it have been few. The rapid settling back of prices after the jump of last week to not only the points they started from, hut also, in many cases, lower ones, has caused a feeling of despondency and rendered the market decidedly blue.

The early days were characterized by weakness, dullness and a steady decline. There was no severe depreciation, bnt the constant output of stocks by insiders drove all animation and buoyancy from the market. It is hard to say wbat the stock market is to do. Evidently the insiders do not intend to allow any very heavy advance in the immediate future. Probably not nntil the arrangements have been completed for the cross-cutting in the Sierra Nevada.

This nncertainty of the market has kept up the soft, weak feeling till the close, the dealers seeming not to fully comprehcnd the situation. We can hardly hope for a live market before the beginning or perhaps the middle of April. By that time the machinery, etc., for extensive exploration in the Comstocks will be in readiness, and the cross-cutting noted above will be under way. A large and booming market will surely follow the expected discovery of a new bonanza of ore. Bodie looks as though it would furnish prominent mines for speculation during the spring. The Northern Belle, Hillside, Highbridge and others are looking splendidly, extensively shipping bullion, and doing what few other mines are—paying their way—all of which tends to draw the eyes of speculators in their direction.

The ahrupt and unexplained termination, on the 5th instant, of the negotiations pending between the mining companies and the Sutro Tunnel company has had a depressing effect upon the so-called "water miue" shares, a large proportion of which are supposed to be held hy the bonanza firm and their friends. This result, though not wholly unlooked for, is unfortunate all round, as it relegates the matter to the courts, involving additional expense and interminable delay, the mines being meantime deprived of the services of the much needed tunnel, and the owners of the latter of the equally much needed revenues that they ought to derive from the mines.

Bullion Shipments.

Since onr last issue, we have noticed the following bullion shipments: Tybo Con., Feb. 24th, $4,059.60; Highbridge, Feb. 28th, $5,296; Martin White, Feb. 26th, $5,330; Hillside, Feb. 28th, $5,320; Highbridge, Feb. 3d, $4,615; Tybo Con., Feb. 28th, $4,095.09.

THE decree in Italy snbjecting vessels arriving from the United States and South American ports to quarantine, has been abrogated.

STEEL rails for the Southern Pacific Railroad Company are coming from Scranton, Pittsburg and Troy.

WORK has been commeuced in Madrid on the buildings for the International exposition of 1880.

A LARGE cave has been discovered in a spur of the Coast Range mountains opposite Roseburg.

DURING the first two weeks in January, 18,000 tons guano were shipped from Pernvian islands.

THE United States Mints recoincd over $2,000,000 in standard dollars in February.

AN avalanche near Marburg, Austria, killed 21 persons and destroyed nine houses.

MEXICO is negotiating for the completion of diplomatic relations with England.

THE Napa Insane Asylum is now quite full, and still the patients come.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MINING NOTES.—*Ledger*, Mar. 1: The Original Amador gives employment to 48 men. The extraction of ore is sufficient to keep 15 stamps in motiou. The deepest level is 800 ft from the surface. The Keystone has erected machinery for sawing logs, etc. There are three saws, a cut-off saw, one for trimming timbers, and a wedge-saw for making the wedges required in the mine. The machinery is run by water-power, by one of Knight's 10-inch hurdy-gurdy wheels. The Iowa claim adjoins the Lincoln and Mahoney mines of Sutter creek. The bonanza met with in the Mahoney is 600 ft from the Iowa line, and runs in a direct line from the latter ground. Allen Tibbetts is the principal owner of the property, and has put 30,000 shares upon the market at 50 cents a share. A shaft reaches down 60 ft. One hundred and fifty tons of the rock has been milled, with fair results for surface rock. The bottom of the shaft is covered with strata of good ore.

OTHER ITEMS.—Volcano Cor. *Dispatch*, Mar. 1: The Oriesbach mine, Pioneer creek, has about 200 tons of quartz, averaging $60 per ton, now upon the dump, the crushing of which is in operation. The Harmon boys have two ledges on the same lode, from which they are taking out very rich rock. Joe Le Duc has 30 tons of rock out at his claim, which will average $50 per ton. A new quartz lode has been struck in the canyon just below town by T. Gillick. The ledge is six ft wide, and the pay streak two ft. The Downs mine has just had a clean-up after a 14 days' run, the yield amounting to $6,800. The Fort Ann mine has a drift 75 ft in the new shaft, and shows a vein of very rich rock, which prospects well. The old Siebenthaler mine has been relocated by W. Rose, of San Francisco, and soon will be in active operation. The Confidence mine has been bonded by San Francisco parties, and the necessary hoisting machinery for working it is now on the road. Water is scarce here at present, yet a few of our placer claims are being worked with good results. The Philbrook & Starling mine, on Pioneer creek, is being worked with very satisfactory yields to its owners. "Lucky Dick" also has a claim at the same place which is doing finely. The Gold Gravel mining company's tunnel is in 1,300 ft. A 10-stamp mill for cement is now on the road; to be used on the Forty-Nine placer claim.

BUTTE.

MAGALIA G. M. CO.—*Mercury*, Feb. 28: The claim is reached by a tunnel 700 ft long, possessing an incline of 500 ft, and is, to all appearances, an old river channel. In width the channel or lead averages about 75 ft, and the gravel deposit averages from 18 inches to four ft in depth. Fifteen thousand dollars have been expended by the present operators in reopening the mine. The capital stock of the company is divided into 100,000 shares, of which Mr. Barrett owns one-eighth. Two miles of ditch, carrying 175 inches of water, are owned by the association. They estimate the pressure at 70 ft. The gravel is excavated at the bottom of the tunnel, hauled to the surface in cars and then washed. Samples of the dirt appear to be of a clayish character and quite hard; it crumbles after being exposed to the air. Seventy-three ounces of gold were taken out during four days of last week.

KIMSHEW NOTES.—Miners think the quantity of snow sufficient to ensure a bountiful supply of water the coming season. Operations have been resumed by the Snow company with a force of six men, which will soon be increased to 10. Ryan & Co., the principal mining operators on Little Kimshew, have not began work yet, but expect to within a week or so. Quite a number of new claims have been located in these districts the past winter, and the hills are swarming with prospectors.

MINING IMPROVEMENT.—Brock & Taber have received an order from the Vermilion Gravel mining company for 2,000 ft of 7-inch and 1,000 ft of 11-inch water pipe, the same to be made of No. 16 iron. The ground belonging to this company is located in what is known as Forbestown ravine, and has been worked as far up the gulch as the present water supply will admit of. In order to get a further supply of water it is necessary to force the same over a ridge of 300 ft elevation on one side and 200 on the other. A Keep pump, weighing 15 tons, will be located at the base of this ridge, from which water will be forced through the 7-inch pipe to a reservoir on top of the hill, from which the 11-inch pipe will convey it to the claim. The reservoir will hold sufficient water to run a 100-inch stream for 12 hours.

BUTTE CREEK.—Helltown is a first-class mining camp. The Shepard ditch is now completed to Whisky Flat, where one-half of the 4,000 inches it contains will be piped on to the west side, and the other down on the gravel hill of the east side. Work on the Whisky Flat claims will be resumed very soon, as the suit between Fred Stryker and the Maurice estate has been decided. Mary's Flat has its ditches, flumes and pipe all in readiness for the water. Paradise Flat is being worked by Mattby & Rister. Adams & McIntyre's hill claim has paid about 300 ounces; four months' work by three men. Hupp's hydraulic claim is now in operation, with every prospect of its former success.

MONO.

UNIVERSITY.—*Standard*, Feb. 28: A progress of 16 ft has been made in the drift on the 100 level; total length 200 ft. The ore body in this level has increased to two ft in width. The drift on the 200 level is now in 23 ft. The ore has changed somewhat in character, being now all fine decomposed quartz, and of the full width of the drift.

BULWER.—The south drift, 380 level, has been advanced during the past week nine ft; total length, 174 ft. The ledge is two ft wide and looks well. The west crosscut from the drift is in 15 ft. At 10 ft from the drift a fine ledge was cut, one ft wide, of very good ore. The ledge in the upraise is two ft wide, of very fine ore. The Stonewall stopes continue to look well. There has been no particular change in the tunnel, which is still in good blasting ground.

SYNDICATE.—The south drift from the east crosscut was advanced seven ft during the week. Crosscut No. 2, east, is in 44 ft. During the past week three small seams of quartz have been cut in the latter. The formation is looking favorable, and it is expected that the ledge will be cut at an early day. The west crosscut has advanced 21 ft, in soft porphyry. The winze on the Osceola vein has been sunk 11 ft; total depth below the tunnel floor, 181 ft. The vein is three ft wide, of good milling ore.

SOUTH BULWER.—During the week good progress has been made in the work of development. The 350-ft crosscut has been advanced 14 ft; total, 38 ft. The ground in the face is hard blasting porphyry, and progress is necessarily slow. This crosscut will be pushed ahead as fast as possible to strike the ledge discovered in the 200-ft crosscut. During the past few days, important developments have been made in the 200 level. A new ledge eight ft wide has been cut. It is soft decomposed quartz and clay, and some of the ore prospects very nicely.

BLACKHAWK.—The new shaft is down 291 ft. The bottom is in a mixture of sandstone boulders, clay and quartz, all of which will give a prospect in gold by the horning process. The west crosscut on the 220 level is in 40 ft. At a point 34 ft west of the shaft, a vein of quartz was cut five ft in width, between well-defined hanging and foot walls. The ledge stood at an angle of about 85°, pitching west. A drift has been started south, and the quartz is being raised to the surface and put on the ore dump. The vein is a strong one, four or five ft in width, and ore taken from it at present resembles the rich rock from the Stonewall lode on the other side of the hill. It is fairly "splashed" over with free gold, with dark spots similar to the Stonewall rock. This ledge was cut in the shaft 120 ft from the surface, pitching west. Another ledge, wider and richer, was cut 110 ft from the surface, larger and richer at that depth than the Warren lode, on which the drift is now being run, which is yet to be cut by the crosscut on the 220 level. Between the two ledges in the shaft was found the only hard rock encountered in sinking, and this same intensely hard rock, only much harder, is now found west of the Warren.

BENTON NOTES.—Cor. Inyo *Independent*, Feb. 28: The Comanche mill has started once more, under the management of Robert Burnham. The mill is working over old tailings, some of which have been lying here for several years. They yield considerable quicksilver, as well as a good profit in bullion. Burnham has a process, partly his own, by which he gets a better result than the mill has been able to show heretofore. The Tower mine has been put in working order. A piece of rock from a cave on the lower drift assayed $4,680 per ton. The Josephine tunnel is in 110 ft, and the rock averages $40 in gold and silvar; one piece went $700. In Clover district little is being done at present. The claims are owned by prospectors who depend upon their muscle for capital. J. H. Taylor has a claim, the Oro Fino, on which he sank 46 ft, striking a ledge 45 ft wide, and the thickness is not yet ascertained, as work had to be suspended on account of lack of funds. Assays at the bottom showed $45 in gold, and $20.81 in silver. J. N. Kellogg has a very fine claim, upon which a tunnel extending 180 ft taps the ledge 60 ft under the surface. The Gray Eagle shows a small vein assaying $200. The Wasp, owned by Edward Taylor and J. O. Wheeler, is a large, well-defined lode. The cap-rock shows $19.50, though there has been nothing done to develop this valuable claim. There are over 30 good locations in the district.

NEVADA.

THE CROSBY & OLIVE.—*Transcript*, Feb. 28: This mine, originally owned by John L. Williams, was last year purchased by the Messrs. Crosby and Joseph Olive for $20,000. The claim comprises 3,000 ft on the Providence lode, south, and two other veins. The present owners have erected hoisting works, consisting of a 30-horse power engine, 12-inch stroke and a boiler 36 inches in diameter. The pump is a powerful one capable of discharging 25 inches of water. The rock shows well most of the way in the north 100 level, considerable ore having been stoped out. The vein is in and out at places on this level, but in this drift shows two strong chutes of rock. There has been some crosscutting done on this end of the level, showing the vein to be well confined. Retracing his steps to the southward he traveled 160 ft in the south drift of the 100 level. In the head of this drift the vein is three and one-half ft thick and looks well. At this point a large volume of water, about 18 inches, pours through the rock, and evidently comes from a heavy ore vein farther south. This can be properly classed a contract vein, has a vertical dip of 40° to the east, and runs northwest and southeast. There has been extracted 1,000 tons of fine ore, exclusive of surface working. The ore is of free gold and sulphuret nature, and cannot be called refractory.

MINING NOTES.—*Foothill Tidings*, Mar. 1: Very rich quartz was taken out of the Scadden Flat mine lately, a piece the size of a double fist containing gold estimated at $50. A clean-up of 55 loads of quartz, taken out by tributers, in the south workings of the Rocky Bar mine, paid upwards of $60 per ton. New York hill is said to be looking better than for sometime. John Bryan has a new location on the top of Oshorn hill called the Electric Wand, and is at work opening it up. The Wyoming mine never looked so well as now. Last week a clean-up of $2,700 was made after a three days' run. Rich specimens have recently been found in the Deadwood mine. The Eureka Lake company at Moore's Flat have decided not to pay new men employed more than $2.50 per day and the Miners' Union there has been revived to resist the reduction. In Watt blue gravel they have stoped east drift and drifted west 12 ft. Bedrock granite and pitching. Drifted 15 ft east last week. The tunnel of the Planet Gravel company was extended 17 ft last week; making the total length 1,624 ft. It is believed that the ore now coming from the Deadwood mine will not yield less than $40 per ton.

PLACER.

SHURTLEFF QUARTZ MINE.—*Herald*, Mar. 1: The main shaft is now down 205 ft. The tunnel of 530 ft strikes the shaft 140 ft from the surface. At the lowest level a drift has been run 85 ft east and west from the shaft. From this drift 55 tons of rock have been raised, which milled $30 per ton, or the nice sum of $1,650. During the last two weeks Mr. Shurtleff has been stoping above the lowest level, and has taken out 40 tons of rock which will average the sum of $50 per ton, or in amount, the sum of $2,000. The lead is about two ft in thickness, and through it there is a streak of very rich rock, which will mill at from $500 to $1,000. The rock which is in this rich streak is saved separate from a milling quartz as specimen rock. Mr. Shurtleff owns 2,000 ft on this lead, from Smith's ravine on the east to North ravine on the west. The expense of hauling and milling the quartz is $4 per ton. The whole expense of working the Shurtleff quartz mine is not over $6 per ton.

PLUMAS.

PLUMAS EUREKA.—Alioth Cor. *National*, Feb. 22: The tailings from both of this company's mills are run in flumes to a system of arastras, 26 in number, strung along the bank of the creek in as close proximity as the declivity will allow for the power necessary. They are driven by the common Mexican horizontal wheel, but are put up strong and good. They are owned and operated by Italians, who, besides a monthly rent, have paid a handsome bonus for the privilege. The upper mill has eight stamps more than the other, or 48 in all. The concentrators, 22 in number, are the patent of W. H. Patton, the civil engineer of this and the mills under the control of Cross & Co. The motion to these concentrators is imparted by a worm wheel. The concentrated stuff is roasted in a Bruckner furnace. The old, or snow-shed tunnel supplies the old mill. The new has its supplies in part from the new tunnel lately run on the level of the lower Mammoth tunnel. It is 200 ft below the other. Ore is also brought from the middle ledge and '76 mine, the latter yielding gold of a finer quality than any other lead upon the mountain. Besides the three lodes named, they have built a house for the workmen, and started a tunnel in the Rough & Ready ground, nearly a mile south, with a view to tap the above-named mine, as well as two others known to be upon that side. There is more ore in sight now than ever before. The lode develops better as depth is made, and there is drainage yet by tunnel 500 or 600 ft below the present workings. There is a continuous body of quartz on the upper level of 850 ft in length. The middle and the '76 lodes being situated higher up, are capable of being drained over 1,000 ft in depth.

TRINITY.

NEW RIVER MINES.—*Journal*, Mar. 1: All the miners are busy. The Eagle Creek company have begun sluicing. The Slide Creek company have an abundance of water, and are running their saw mill day and night. Their claim will be in working order in a short time. They have some very rich ground, with a fair prospect of striking an old channel. The same company intends taking water from the main river and conveying it by ditch and flume two and one-half miles down stream to Rattlesnake bar, where fine prospects have been obtained. This company have a new ditch cut, and mill framed and irons ready to set up as soon as spring comes. Another company propose to take a ditch from the river for the purpose of conveying water to the bar at the mouth of this river, which contains 25 acres of mining ground. On a portion of this bar there is a gravel bank from 40 to 60 ft deep. This will be the most extensive mining enterprise on either Trinity or New river. The water will be carried across the river, below the mouth of this stream, and then along down the Trinity as far as David Gray's place, five miles from where the water is taken from the river. This flume and ditch will cover mining ground enough to last the company a lifetime. The bars are all high, and afford from 40 to 75 ft "dump" for rocks and tailings.

NEVADA.

WASHOE DISTRICT.

In the absence of our usual Washoe correspondence we publish letters from the various mine Superintendents of the dates mentioned:

JULIA.—Letter of 1st: Good progress has been made in reducing the accumulated water in main incline below 1800 level, which stands 200 ft below the latter level, or 83 ft above the sill floor, 2000 level. All preparations are completed to discharge the water in the Sutro tunnel on receipt of instructions from the main offices in San Francisco. Winze sinking from 1800 level, south drift, up to present time, has made slow progress on account of the intense heat, but the present aspect bids fair for better progress in the future.

WARD.—Letter of 1st: Our east crosscut, 800 level, has been advanced 26½ ft for the past week; total length, 475 ft. Material encountered, streaks of various widths composed of lime quartz, soft vein porphyry; also streaks of solid block bird's-eye porphyry. Have 225 ft yet to drift to reach the downward continuation of the vein, which crops out so prominently on the surface and east of main shaft. Everything about the mine working well.

CHOLLAR.—Letter of 1st: The Chollar-Norcross-Savage shaft has been sunk 11 ft during the past week; the water hoisted from the bottom with skeets has averaged 85,000 gallons per day.

SILVER HILL.—Letter of 1st: During the past week have sunk and timbered the main incline 16 ft. The main east crosscut on 1100 level has been extended 38 ft. The face is still in porphyry carrying considerable iron.

OPHIR.—Letter of 1st: The repairs on the pump-rod and connecting rod at the head of the main incline were completed Monday, when hoisting the usual amount of ore was resumed. But owing to the water, work was not resumed in the incline on the 2200 or 2100 levels until yesterday. During the past week we have put in a new pump-bob at the 600 station to take the place of the old one, which was too small. We are still at work repairing the main shaft above 1465 station. We hope to have this work completed in another month. The flow of water from the Union Con., east drift, continues to decrease, and is now not more than two and one-half inches.

MEXICAN.—Letter of 1st: On our 2000 level the main north drift has been extended 50 ft during the past week; total length from our south line, 523 ft. The material passed through and in the face is hard rock, which blasts well. The flow of water from this drift has increased to about two and one-half inches. On our 1600 level the Union Con. joint winze has been sunk and timbered 12 ft; total depth, 256 ft on the slope. No change in material passed through.

BELCHER.—Letter of 1st: The main incline has now attained a depth of 88 ft below the 2560 level, having been sunk 21 ft the past week. The south drift on the 2560 level is in a distance of 186 ft, 54 ft having been added the past week. Everything in and about the mine is going along smoothly, and crosscutting can be commenced any time. In the course of about two months the main incline will be deep enough to admit of opening another level.

HALE & NORCROSS.—Letter of 3d: The winze from our 2000 east drift is down 60 ft. The water this morning is 21 ft below the 2000 station.

EXCHEQUER.—Letter of 3d: The north drift has been extended during the past week 20 ft; total length, 207 ft. The formation on this level is a kind of vein porphyry with streaks of quartz.

GOULD & CURRY.—Letter of 2d: During the week crosscut No. 4 west was extended 25 ft, and is now in porphyry. Crosscut No. 3 east is in 308 ft, having been advanced 25 ft during the week; the face is in hard blasting rock. East joint drift, 1700 level, is in 568 ft, having made 38 ft. The face is in good working ground. The Osbiston shaft was sunk 10 ft. The flow of water continues very strong. Total depth of shaft, 485 ft.

SAVAGE.—Letter of 3d: No work has been done in the mine for the past week, except some little repairing in the vertical shaft and incline. We have disconnected our donkey pumps and have allowed the water to raise to our tank, 40 ft below the 2000 level, thereby making a great saving in the consumption of wood. All the machinery is in good working order.

BEST & BELCHER.—Letter of 2d: Since my last report west crosscut No. 3, 1000 level, was advanced 24 ft, and is now in 128 ft from the winze. The face is still in vein matter but shows less quartz. The 1900 level joint winze is down to the 2000 level, and the station cut out and timbered. This work will be stopped for the present. The joint drift, 1600 level, was extended 38 ft and is now in a total distance of 568 ft. The face is in easy working ground and perfectly dry. Osbiston shaft is down 485 ft, having made 10 ft during the week. The water is still strong.

CON. IMPERIAL.—Letter of 2d: Our station chute for south winze at our 2600 level has been finished and we are now drifting north and south on this level. Have advanced the north drift 10 ft. The south drift to connect with Jacket 2400 level has been advanced 10 ft. The formation in face of both drifts is porphyry with streaks of quartz. We are also engaged in repairing and altering the station at our 2135 level of the joint winze. No change in flow of water from the face of joint drift east 2400 level.

BULLION.—Letter of 3d: On last Monday connection was made between our 2150 and the 2000 level of the Imperial. This connection has greatly cooled off this drift, the temperature falling off at the rate of one and half per cent. per day. We will put this level in order as rapidly as possible, and this week will commence crosscutting east. The 1840 level has been cleaned out and an east crosscut started. During the past week no work has been done in the incline, it being deemed not advisable to resume sinking until the new air compressor is in place. The excavation for the foundation of the new air compressor is completed and we expect to have the entire work completed in 30 days.

EUREKA DISTRICT.

THE HAMBURG.—*Sentinel*, Mar. 1: The intermediate drift, 130 ft below the 250 level, was advanced 22 ft during the past week beyond the upraise, following the vein, which shows a material improvement, and is yielding a considerable amount of good ore. On the 600 level the west crosscut was advanced 15 ft; making a total from the south drift of 150 ft, with no special change. South drift from crosscut advanced 18 ft, making a total of 85 ft; is in favorable vein matter, with bunches of iron and low-grade ore. The winze was sunk nine ft, in very hard rock, but the bottom is now in soft material, which works well. On the 450 level the east crosscut, 330 ft north of turn-table, is in 11 ft.

THE EUREKA CON.—Work has been carried on with good progress in extending drifts, etc., there having been 204 ft completed during the week. The new pinion is in place, and hoisting through both compartments is going on as usual. Furnace No. 3 has started up, and is running first-rate. The following work has been done on the several levels: Northeast drift, on fifth level, from cave continued three ft, and is now in 125 ft; started raise from south drift and made 10 ft. East drift, on seventh level, from chute continued 13 ft, and is now in 139 ft. West drift, on 11th level, from ore chamber continued 20 ft, and is now in 89 ft. East drift, on 12th level, from crosscut No. 1 continued 27 ft, and is now in 364 ft. East drift from crosscut No. 2 continued 30 ft, and is now in 111 ft. Drift from raise continued 25 ft, and is now in 145 ft. North crosscut, on 13th level, continued 42 ft, and is now in 66 ft.

NOTES.—A large water flume is being built by the K K down the canyon through their waste dump. About 200 tons of ore are shipped daily by the Richmond. El Dorado mine, Prospect mountain, is now worked on lease by six men. The Silver State and Original Baltic mines have been bonded to some Eureka capitalists. Rapid progress is being made on the Phœnix incline. The Jackson is still shipping its usual quantity and quality of ore to the Meta-

[Continued on page 156.]

On Artesian Wells.

[Read before the Section of Geology, Mineralogy and Mining, by CHAS. D. GIBBES, December 14th, 1878.]

In the investigation of all matters of natural science there is none of more importance to this State than the supply of good pure water, not only adding to the health of the inhabitants but to the value of lands on the arid plains. The subject of artesian wells is a very important one to this city at present, and I hope it will receive an early investigatiou hy the memhers of our section. The object of this paper, however, is not to make a report on artesian wslls, for I have heen very much disappointed in obtaining the information that I sxpected.

In 1875 I sent out circulars to most of the well-horers in the State, requesting a record of the different wells to be sent to me, to he compiled in a report to the Academy. Some fsw answered, saying they would do so in a short time; hut up to this time have not been heard from. I therefors merely propose to state a few facts that have come under my ohservation; and, although not a geologist, give my views on the subject, with the hope of drawing out the opinion of other memhers who are hetter qualified.

First—what is an artesian wsll? Webster's definition is: wells mads hy horing into the earth till ths instrument reachss watér, which from internal pressure flows spontaneously like a fountain. Ure says: under this name is designated, a cylindrical perforation, hored vertically down through one or more of the geological strata of the earth, till it passes into a porous gravel hsd containing water, placed under such incumbent pressure as to make it mount up through the perforation, either to the surface or to a bight convenient for the operation of a pump.

Ths hot springs that flow out to the surface in many parts of ths world, rising from great depths, are natural artesian wells. The first overflowing wells wers made in tbs French province of Artois (Latin *Artesium*), whence the name of artesian. They have long been in use in that country.

Wells in San Francisco.

The city hase from which the elevation of the streets is reckoned, is the level of the wharves on the city front, it heing six feet and seventenths ahove mean high tide or level of the sea, and the grade is given on a large map of the city, at the intersection of the streets.

From the information published in the *Call* and what I have heen ahle to collect, water has heen ohtained at a depth of from 80 to 360 feet, which is the deepest well in the city of which we have any record, although there may he others deeper. This well is at the Pacific Iron Works on First street (which is hut a few feet ahove the sea level), yet it affords loss water than many wells only 140 or 150 feet deep.

Although the supply from each well in the city is ample for the purpose for which it was constructed, yet in comparison with the depth and amount of water furnished hy some wells, it is mere prospecting; for as yet no large stream with a good head or known source in an elevated region sufficient to furnish a supply for the city has yet heen struck. It is possihle when the drill penetrates through the sandstone stratum into the other cretaceous rocks, a large stream of water may hs ohtained; hut nons from the Sierra Nevada unless we reach the geological formation of that region. It is true that we have a good supply of water at a short depth in the reservoirs of the alluvial deposit underlying the city, hut they appear to he disconnected and local in their character, as I will endeavor to show; and I will now call attention to a few wells represented in diagram *A* on the map marked grade of Van Ness avenue. It extends from Sacramento street, south to Market, then on to Folsom. The elevation heing marked ahove at the intersection of the streets, and the depth of the wells at the bottom of each.

A—Grade of Van Ness Avenue.

The explanation of diagram *A* is as follows: 1, Market street, elevation 44 feet; 2, old well at City Hall, depth 195 feet; 3, new well at City Hall, depth 180 feet; 4, well at ths corner of Van Ness avenue and McAllister street, 130 fest; 5, well at the corner of Van Ness avenue and Sutter street, 206 feet; 6, wells at Sutter Street Stahles, 180 feet, and Caseholt, 152 feet; 7, wells at Chicago Brewery, 166 feet; Graves' well, 160 feet; 8, sandstone; 9, Bradhury well, 194 feet; Lyle well, 163 feet; 10, Hayward well at the corner of Sacramento and Polk streets, 140 feet; 11, water line; 12, city hase; 6.07 feet ahove mean high tide; 13, 13, sea level.

Commencing at the corner of Sacramento and Polk, elevation, 170 feet, is the Hayward well, 140 feet deep, ths hottom heing, yon perccive, 30 feet above the city hase. Ths elevation at California and Van Ness is 180 feet. On the the east side a little helow the grads is the Bradbury well, 194 feet deep, the hottom heing ahout 20 feet below the hase. Opposite, on the west sids, and ahout 10 feet above the grads is the Lyle well, 163 feet deep, ths hottom being about 27 feet ahove the city hase. I call attention more particularly to these three wells as they are shown in another diagram. Next are the following wells: Graves', corner Van Ness and Pine, elevation 180, depth 160; Chicago Brewery, Pine near Polk, elevation ahout 153, depth 166; Sutter Street Stahles, corner of Polk and Bush, elevation 142, depth 180; Caseholt's, corner of Larkin and Bush, elevation 150, depth 152; corner of Van Ness and Sutter, elevation 162, well 206 feet; corner of Van Ness and McAllister, elevation 58, well 130; City Hall, elevation ahout 50 feet—old well 195 feet, new well 180; Stevens' well, corner of Folsom and Eleventh streets, elevation 16 feet, depth 144 feet.

These wells are also shown in their relative position on a city map, hy red circles. Van Ness avenue, by a hlack liue; Octavia, Jones and Sacramento, hy red lines; Market street, hy a green.

Diagram B.

Explanation of figures in diagram *B:* 1, Octavia street, elevation ahove city hase, 280 feet; 2, Gough street, 270 feet; 3, Franklin street, 220 feet; Lyle well, 163 feet; 4, Van Ness avenue, 180 feet; Bradbury well, 194 feet; Hayward well, 140 feet; 6, Polk street, 160 feet; Larkin street, 180 feet; 7, Hyde street, 210 feet; 8, Leavenworth street, 260 feet; Jonss street, 300 feet. Lower stratum sandstone; next indurated sands containing water; next clay; and upper stratum sand.

This is a cross section on California street from Octavia to Jones streets, showing the relative position of the three first mentioned wells, and the formations through which they have passed.

The elevation of Octavia street, shown to the west, is 280 feet; that of Jones, on Clay street hill to the east, is 300 feet; and Polk street, the lowest in the hasin, is 160 feet. The Bradhury well, in the center, 194 feet, does not reach the so-called hedrock; hut the Hayward well on the east, 140 feet deep, and the Lyle well on the west, 163 feet, do reach it.

This hedrock is said to he serpentine, but I have not heen able to ohtain any specimens from the wells. Mr. Lyle, however, informs me that it is the same as the ontcrop on the hills. He also says that his well passed through ths following strata: sand, 30 feet; clay, 53 feet; and what is called sandstone, 80 feet. In this sandstone the water percolates, and the pipe through the sandstone heing perforated, the water rises in it, but it does not come to the surface. In his well it is 56 feet helow the surface, and in others about the same level. It is represented iu the diagrams hy a hlue line across ths wells. The sandstone forms a reservoir. There is certainly no stream at the bottom.

Mr. Lyle's tank holds 16,000 gallons, and is filled in 11 hours hy pumping with a hot air engine; and the supply appears to be the same.

Diagram F

Represents a section hetween Octavia and Gough streets. On examining the outcrop on the hill at Gough street, betweeu Sacramento and California streets, I find it to be sandstone, (see specimen marked *A*). This sandstone must he the hedrock of the hasin; clay and sand ars also seen ahove it.

The sxplanation of diagram *F* is as follows: 1, Fulton street, 67 feet; 2, McAllister street, 70 feet; 3, Tyler street, 81 feet; 4, Turk street, 102 feet; 5, Eddy street, 140 feet; 6, Ellis street, 168 feet; 7, O'Farrell street, 200 feet; 8, Geary street, 200 feet; 9, Post street, 200 feet; Sutter street, 220 feet; 10, Bush street, 220 feet; 11, Pine street, 240 feet; 12, California street, 280 feet; 13, Sacramento street, 320 feet. From 1 to 7, serpentine; from 7 to 13, sandstone.

Diagram G.

The following are the figures on diagram *G:* 1, Franklin street, 170 feet; 2, Gough street, 196 feet; 3, Octavia street, 200 feet; 4, Laguna street, 180 feet. From 1 to 2, sand; from 2 to 3, serpsntine.

At the cut on O'Farrell street, the serpentins can hs seen with an eastsrly dip of 25° or 30°; and opposite, on the east side of Gongh street, is a sand hill 40 or 50 feet high. I was informed hy a man who said that be had lived there 17 years, that no serpentine was ever seen west of this outcrop for a long distance.

Wells in the Bay.

Artesian wells are common on the peninsula and in Santa Clara valley; hut soms of you may not he aware that wells have also been sunk in the bay of San Francisco. Ths enterprising firm of Morgan & Co., 87 California market, have oyster heds at suitahle locations on the west side of the bay, for a distancs of 17 to 18 miles. Each location is fenced in to keep the sting ray from eating the young oyster, of which ahout 10 car-loads are imported from ths East every spring and planted in these heds. The size of the young oyster varies from half an inch or more. The firm have three stations, at which men ars employed to take cars of the oyster beds. One is opposite Millhrae, ahout three-quarters of a mile from the shore, consisting of a wharf ahout 20 fest high, with a houss on it, and is called ths Millhrae station. The next is Belmont station, on a small island at the entrancs of Steinhergen's creek, opposits Belmont. The third is Dumharton station, ahout ons mile south of Dumharton wharf, and over a mile east of the western shore. Thers is also a wharf ahout 20 feet ahove the hottom of the hay, and has a house on it. Iu August, 1878, a well was hored at this station, 212 fest deep from the top of the wharf; it discharges a stream of good, sweet drinking water two feet ahove the wharf, and is supposed would rise much higher if the pipe was carried up. The water of ths bay at the wharf, is 10 feet deep at mean high tide, and overflows the salt marsh a foot or more; so that we may call the flow of the well at 10 to 12 feet ahove the marsh.

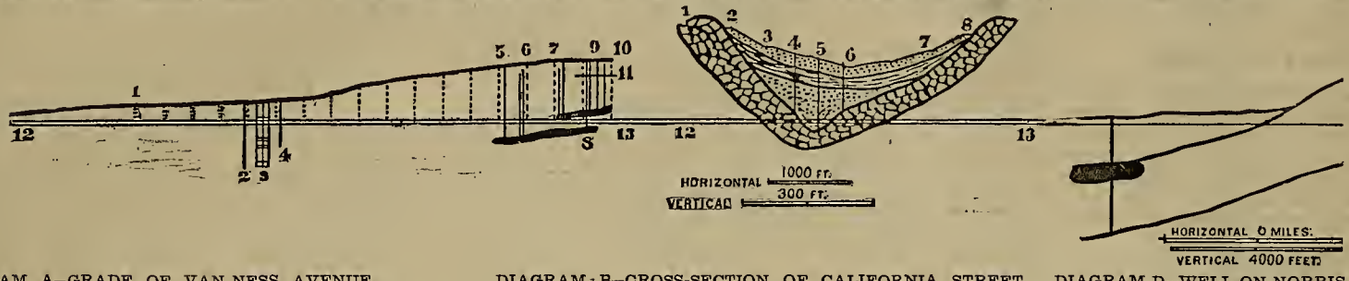

DIAGRAM A—GRADE OF VAN NESS AVENUE. DIAGRAM B—CROSS-SECTION OF CALIFORNIA STREET, FROM OCTAVIA TO JONES. DIAGRAM D—WELL ON NORRIS GRANT Depth, 2,107 Feet.

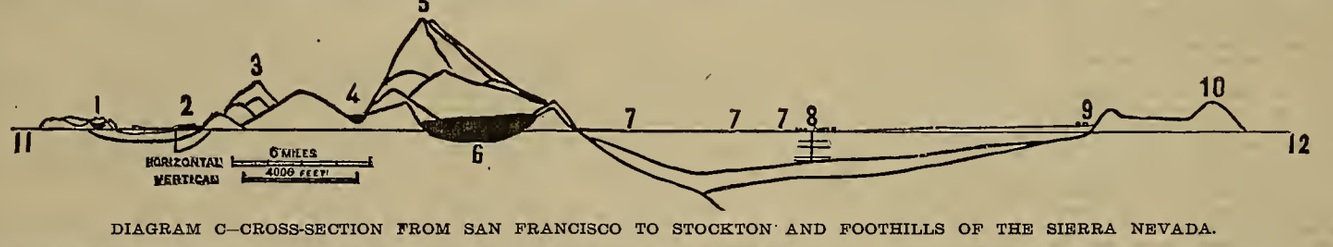

DIAGRAM C—CROSS-SECTION FROM SAN FRANCISCO TO STOCKTON AND FOOTHILLS OF THE SIERRA NEVADA.

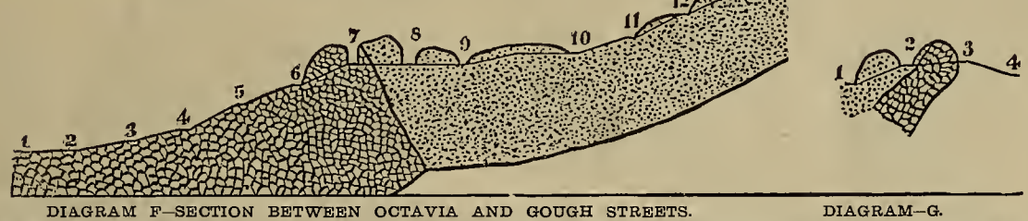

DIAGRAM F—SECTION BETWEEN OCTAVIA AND GOUGH STREETS.

DIAGRAM—G.

Construction of the Well.

The well is constructed in the following manner: Of No. 16 hlack iron artesian well pipe, 11 inches in diameter and 2 feet in length; also another a size larger to slip over the first, and hreak the joints a foot each way. This double pipe was lowered down through the water and mud 42 feet from the top of the wharf, and sunk into the clay a foot or more; the water and mud is now pumped out; and two smaller double pipes, one of nine inches and the other of seven inches diameter, and made in the same manner, are inserted. The spaces between the three pipes are filled with cement, forming a solid pipe of six thickness of iron and two spaces of cement; and the horing of the well is now commenced. The space between the seven and nine-inch pipes, however, is not filled with cement until the well is finished, as the pipe has to follow the auger. This well, like those in the Santa Clara valley, 6 to 10 miles distant from tide water, is affected by, or rather, rises and falls at the same time as the tide. The hight of the rise and fall at Dumbarton have not yet heen determined for want of proper pipe.

Phenomena.

On Saturday night, Septemher 28th, this well at the Dumharton station commenced to discharge muddy water, and continued doing so two days or more; which it had never done before; it is now flowing as usual. On Sunday the 29th, ahout 6 P. M. (20 or 24 hours later), you will remember a strong shock of an earth-

[Continued on page 153.]

The Engineer.

Locomotives Without Fire.

Machines on tbe above-named principle are now at work on the tramway from Ruell to Marly, near Paris, and with very satisfactory results. The system in use ie one introduced by M. Francy, an engineer, and is based on the fact that water boils at a lower temperature proportionately to the production of the atmospheric preseure. Most of our readers are aware that altbough water requires a beat of 212° Fahr. to boil at tho level of the sea, a much lower temperature is sufficient to produce the same effect ou the top of a mountain We will now explain how that physiological fact is practically employed. Into a reservoir of thin steel—wo cannot call it a boiler, for it bas neither fireplace nor firo—ie introduced water at a temperature of 200° Fahr., and then covered hermetically. The steam it gives off at once fills up the superincumbent space, and produces a pressure of 15 atmospheres. As long as any of the vapor is turned on for moving the machine, the pressure is reduced, and tho water then begins to boil, producing a fresh supply of steam. Of course, that process is of but limited extent, as, at the commencement, the liquid only contained a certain amount of heat, which is gradually diminished as the reproduction of steam takes place at lower temperature by the exhaustion of the superincumbent pressure. So far, a machine of this description would be obviously totally inadequate to any very prolonged journey. But for short transits it has been found extremely serviceable. As the amount of pressure required to work the engine is only five atmospheres, a series of valves are so arranged as to prevent a greater amount of force issuing from the reservoir than is necessary, and thus retaining, as far ae possible, the heat originally contained in the water. The driving part of the machinery is nearly identical with that of ordinary locomotives, with a few modifications with the purpose of guarding against useless waste of the heat originally introduced into the reservoir.—*Galignani's Messenger.*

Excavations and Foundations in Sand. M. Plocq has published an interesting paper upon the recent harbor improvements at Dankirque and Grovelines. There are 10 sluices for controlling the fresh and ealt waters of the districts for various purposes of maritime and domestic economy, as well ae for tbe wants of the military service and for defensive operations in time of war. The sluices are built in a soil which is wholly made up of a pure sand of flour-like fineness, reaching to a depth of from 50 to 65 fcet below the lowest tidal levels. The works were all executed by the help of coffer dams, in preference to dredging, and the preparations were so thorough that it was always easy to work in dry sand even at the lowest foundation levels. The total cost was less than half what it would have been by the old method of dredging, and the saving of time was in about the same ratio.—*Ann. des Ponts et Chauss..*

Elevated Railways not Detrimental.—Instead of proving tbe terrible detriment to property which was predicted, the elevated railways in New York city, seem to be conceded to bave greatly increased trade on the streets upon wbicb they run. So marked is the movement of tbe retail business from Broadway to Sixtb avenue, that heavy property owners on the former tboroughfare are inclining to the opinion that they must bave an elevated road also. Tbe complaints in regard to the noise of the trains seem to have nearly ceased, while tbe bnndreds of thousands of people who reside in the upper part of the city are full of gratitude for the vast improvement in the means of transportation.

New Tailings Dredger.—The Golden State and Miners' Fouudry, of this city, has recently completed a vacuum dredger for the Slate Creek mining company. The dredger, built at a cost of $20,000, will be used in dredging the streams in the northern part of the State into which the tailings and debris of the past 20 years or more have been run. The dredger takes up the earth by means of a bell-shaped box, from wbich tbe air is exbausted by means of condensed steam, and is capable of lifting 200 square yards of earth per bour. Tbe eartb will be dumped into ebort sluice-ways, conveniently arranged and treated in tbe usual manner.

The Great Hungarian Tunnel.—On tbe 21st of October the great Josef adit at Schemnitz in Hungary was opened. The works have been carried on since 1872, tbe Hungarian government granting £10,000 a year toward them. Tbe adit is over 10 miles long, being some 50 yards longer than tbe Mount Cenis Tunnel. The total cost of the undertaking was £459,900; it was carried out entirely by Hungarian enterprise, and partly with Hungarian machinery.

Engineers are at work running the line for the narrow-gauge railroad on the east side of tbe San Lorenzo river.

Prof. Feser, contrary to tbe generally accepted verdict, announces, as tbe result of a long eeries of experiments, tbat salicylic acid has no value eitber bas a prophylactic or in the treatment of infectious diseases, carbuncles, etc.

Useful Information.

Cutting Glass.

For cutting flat glass, such as wiudow-panes, and for cutting rounds or ovals out of flat glass, the diamond is the best tool, and if the operator has no diamond it will always pay to carry the job to a glazier rather than waste time and make a poor job by other and inferior means. When, however, it is required to cut off a very little from a circle or oval, the diamond is not available, except in very skillful hands. In this case a pair of pliers softened by heating, or very dull sciesors, is the best tool, and the cutting is best performed under water. A little practice will enable the operator to shape a small round or oval with great rapidity, case and precision. When bottles or flaske are to be cut, the diamond is still the best tool in skillful hands; but ordinary operators will succeed best with pastiles, or a red-hot poker with a pointed end. Tho latter is preferred, as being the most easily obtained and the most efficient; and there is no difficulty in cutting off broken flasks so as to make dishes, or to carry a cut spirally round a long bottle so as to cut it into the form of a cork-screw. And, when so cut, glass exhibits considerable elasticity, and the spiral may be elongated like a ringlet. Tbe process is very simple. The line of the cut should be marked by chalk or by pasting a thin strip of paper alongside of it; then make a file mark to commence the cut; apply tho hot iron and a crack will start; and this crack will follow the iron wherever we choose to lead it. Iu this way jars are easily made out of old bottles, and broken vessels of different kiuds may be cut up into new forms. Flat glass may also be cut into the most intricate and elegant forms. The red-hot iron is far superior to strings wet with turpentine, friction, etc.

The Manufacture of Curtain Rings.—In the ordiuary process of pressing or stamping brass, as in making curtain rings, the surface cannot be raised by one blow; it requires a succession of blows. This, however, would make it brittle if it were not prevented by annealing the metal from time to time. In the process of annealing it becomes coated with black scale, which can be detached by means of aqua fortis. Tho process of "dead-dipping" to obtain a dull surface, is conducted by dipping the annealed metal iu aqua fortis (one part of aqua fortis to four of water) till the black scale rubs off easily; hen, after washing in water, it is dipped into acid of double the strengtb. This acid will attack the metal and form a green layer on the surface, wbich really consists of bubbles of gas. Wheu it is well coated it is taken out and washed and rubbed with cold sawdust, and without removing tbe adhering sawdust is plunged into the strongest acid. It is taken out of this almoet immediately, and washed in water containing cream of tartar dissolved, and is lastly placed in bot sawdust.

A Vegetable Green for Confectioners.—It appears, according to one of our French exchanges, that from the grains of raw coffee there may be extracted a beautiful green coloring matter adapted to all the purposes of the cook and confectioner, and which will undoubtedly prove of great value as a commercial product, inasmuch as the number of green colore suitable for such uses, and whicb are not poisonous, is very limited. According to M. Zech, who describes the process of extraction, the coloring matter is obtained in the following way: The coffee grains are crushed and the oil ie extracted by means of ether; they are then dried and agitated with the white of eggs, so as to form a sort of paste, and the latter is exposed for several days to the air. The preseuce of the white of eggs then determines the appearance of an emerald green. A simpler process is to merely moisten tbe crushed and desiccated coffee herries with water, expose them three or four days to the air, and extract the coloring matter by means of alcobol.

A New Writing Multiplier.—A new arrangement for multiplying writing, called the hectograph, has recently been invented in Germany. The hectograph consists of a flat sheet-iron box filled with a gluey mass, upon which, after moistening and drying it several times, a sheet of paper, written upon with a specially prepared ink, is placed and lightly rubbed with the hand. When the paper is raised the writing is found to be transferred reversed to the film of glue, and from tbat film, by simply placing pieces of dry paper upon it and rubbing them, some 50 impressions of tbe writing can be taken in a short time. The negative impression can easily be removed from the film by washing witb warm water, and the latter can be used over and over again for a long time.

Requirements of a Good Boiler Water.—Mr. W. F. K. Stock, in a recent communication to tbe *Chemical News*, defines tbe requirements of a good boiler water in tbe following terms: It should be characterized by: 1. Freedom from any very appreciable quantity of suspended mineral matter. 2. Absence of any trace of mineral acids, or of acid salts, or corrosive salts of any kind. 3. Absence of oily or fatty substances of any kind. 4. And, finally, a good boiler wator sbould not contain more than 30 grains of solid matter per gallon, and not more than the half of this quantity ehould precipitate on boiling under pressure.

How to See the Wind.—Take a polished metallic surface of two feet or more, with a straight edge—a large hand-saw will answer the purpose. Take a windy day, whether hot or cold, clear or cloudy, ouly let it not rain or the air he murky; in other words let the air be dry and clear, but this is not essential. Hold your metallic surface at right angles to the direction of the wiud—*i. e.*, if the wind is north, hold your surface east and west, but instead of holding the surface vertical, incline it about 45° to the horizon, so that the wind striking glances and flows over the edge (keeping it straight) as water over a dam. Now sight carefully over the edge at some minute and sharply defined object, and you will see the air flow over as water flows over a dam. Make your observations carefully, and you will hardly fail to see the air, no matter how cold; the result is even better when the sun is obscured.

Cinder Wool.—A German writer relates his experience with cinder wool as an anti-heat conductor for steam pipes, which tends to show that it is by no meaos indifferent from what material the wool is made. After the pipes had been covered with wool for two years, they were found to be much corroded, and the woolly fibers had become a sintered mass resembling mortar, a change which is probably due to the action of sulphide of calcium.

Good Health.

Excessive Brain Work.

One of the clergymen of Worcester, Mass., in the course of a sermon recently, uttered tbe following cautionary suggestione in regard to immoderate brain work:

"It is a lesson we are all slow to learn—one that has to be enforced by an occasional tbrilling fact—that the most robust physique has its limit of exertion, that well compacted and toughened mental fiber may succumb to undue stress at a single point. A piece of steel wire can bear only a given amount of longitudinal tension. Beyond that limit it snaps. By the annealiug process of intense study or application to exacting business a man's brain gets toughened. It can bear an immense, prolonged strain, but there is an unknown terminus of your powers; exceed that point and the subtle thread of reason snaps. A ruptured capillary on the brain paralyzes that center of thought, and the stalwart, brilliant man of yesterday, full of bope, projecting grand schemes, the pillar of strength to bis family, tbe pride of many, the possible envy of more, is to day an enfeebled or quite broken down victim of intemperate brain work. You might charge me witb au exaggerated idea of tbe perils of overexertion among business men, did not facts justify all I have suggested. Have we not seen some of the brigbtest stars in the cluster of enterprising citizens, of which we are justly proud, wander from their orbit of reason and pass, unless God shall disappoint our fears, into the sbadow of permanent mental eclipse? The saddest feature of this phenomenon is that it seems to fall upon the highly organized, generous, sympathetic natures first. A cold-blooded, grasping Shylock, who cares little for the good name so highly prized by another, appears to be in no danger of such a calamity. Better far to confess poverty, be an honest bankrupt, than be broken down in body or mind under too great exertion to avoid the calamity. Witb emotions of unspeakable pity for every man barassed by his unsatisfactory affairs, I turn to expostulate with the coming generation. Keep a sound mind in a sound body. Do be contented with 'things honest,' with comfortable mediocrity. Husband tbe stock of physical and mental life God has given you, that you may not grow prematurely old—uselese before your time."

Care of the Health.—Health, by some eminent writer, bas been described as "the poor man's blessing—tbe rich man'e bliss." Witb it the most brilliant eudowment of mind, tbe most careful and tborough culture, are of little account in a life-career. In this view early instructiou in all tbat appertains to our physical well being is of prime importance. The earnestness with which some men have stood forth in the van of this cause will be better understood and appreciated in the future tban it is to-day. A distinguished physician pertineutly said, in a recent discussion: "Modern science, in connection with the most advanced views of education, is teaching us more and more every year, the importance of good bealth—of a sound constitution, in order to secure the higbest success in life; and this depends very much upon the proper care and training of the body in youtb. It is becoming evident that physical culture is to occupy a far more prominent position in all our systems of education than beretofore, and must ere long be introduced in some form into tbe regular exercises of all our scbools, seminaries, and higher institutions of learning. We venture this prediction, tbat in no department of educatiou will there be greater improvement for the uext 50 years, tban in a more perfect development of the buman system and harmony of function, between the laws that govern both the mind and the body."

Constipation.

It is doubtful if consumption numbers as many victims that aro stricken down by tbe various diseases that result from habitual constipation. True consumption is an inherited disease. It may remain always dormant, but wheu aroused to action, decay commences at a point circumscribed, and gradually extends—uuless arrested—until so much of the lungs becomo involved that vital action ceases. The evils of constipation result from inattention to the calls of uature, and usually commence witb children whose habits are uot closely looked to by their parents. The processes of nature are always active while life lasts. Wheu effete matter is retained a moment beyond the time its expulsion is demauded, the system commences its efforts to get rid of it. When the natural egress is checked, the absorbents carry the more fluid portions of tbe poisonous mass into the circulation, and it becomes diffused throughout the body. Tbe more solid or clay-like portion is forced into the lower rectum where it becomes firmly impacted, thus cutting off the circulation iu the small blood vessels, causing painful engorgement known as piles and hemorrhoids. A continuance of these troublee ofteu results in fissure, fistula, or cancer. Tho trouble is seldom confined here. As a result of the blood poisoning we almost invariably find more or less dyspepsia, with decided deraugement of the functione of the heart, liver and kidneys, accompained by headache and nervous debility, often verging on paralysis.

Arsenic in Starch—A Singular Case of Poisoning.—For some weeks past a local physician bas been attending a young lady who has exhibited every possible indicatiou of arsenic poison. Her appetite failed her, and her face became of a ghastly pallor, while the features were bloated and the eyee watery, witb swelling of tbe lower limbs. Day by day her body was racked witb intense paiu, and finally her condition became so unendurable that she almost longed for death to put an end to her sufferings. Tbe physician was satisfied from the beginning that she was afflicted witb some disease produced by arsenic poison. But tbe most rigid investigation failed to reveal in what possible way it could have been administered to her. Her food was inspected, the water she drank was most carefully selected from the wells, where no impurity by any means could find its way to it. By the merest accident in the world tbe cause of this remarkable condition was discovered. The doctor happened to be present when tbe young lady's clothes were brought from tbe wash. The singular luster of the linen struck him as remarkable. He inquired who did tbat washing, and was told that an old negro woman whose great skill in polishing linen made her very popular with tho girls. The doctor thought he was now on the road to the discovery, and concluded for tbe nonce to play an amateur detective. He visited the old woman, and soon learned that her "polish" was produced by tbe use of arsenic in the starch. Then the whole case was plain. Tho girl was afflicted by arsenic poison, produced by absorbtion. Being of a peculiar temperament and organization, she incurred a danger which others might have escaped. Respiration aided it, and her bodily susceptibility to the fatal drug conspired to produce the dangerous condition which has just been detailed.—*Denver (Col.) News.*

Poultices.—The common practice in making poultices of mixing the linseed-meal with hot water, and applying them directly to the skin, is quite wrong; because, if we do not wish to burn the patient, we mnst wait until a great portion of the heat has been lost. The proper method is to take a flannel bag (the size of the poultice required); to fill tbis with the linseed poultice as hot as it can possibly be made, and to put between this and the skin a second piece of flannel, so that tbere shall be at least two thicknesses of flaunel between the skin and the poultice itself. Above the poultice should be placed more flannel, or a piece of cotton wool, to prevent it from getting cold. By this metbod we are able to apply the linseed-meal boiling hot, without burning the patient, and the heat, gradually diffusing through the flannel, affords a grateful sense of relief which cannot be obtained by any other means. There are few ways in which such marked relief is given to abdominal pain as by tbe application of a poultice in this manner.

Antiquated Sausages Poisonous. — A few days since two boys named Michael and David McCarthy, aged respectively seven and four years, children of Michael McCarthy, who resides at 19 Ridley street, were taken seriously ill witb violent pains in the bowels. Dr. W. R. G. Samuels was summoned and administered an emetic, but without result in the case of tbe elder boy. Artificial measures were resorted to, and a large quantity of partially digested sausage meat was brought up. The emptying of the stomacb seemed to give relief, and upon a warm mustard bath being administered, the boys were placed in bed, and, though still very sick, appear to be recovering. A piece of the sausage meat, now in possession of the father, shows signs of decomposition, and on analysis Dr. Samuels believes the fatty portion will be found to bave undergone a chemical change, rendering the food poisonous and unsuitable for use.—*S. F. Call.*

MINING AND SCIENTIFIC PRESS.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Boiler Explosions.—No. 1; The Niles Improved Double Hoisting Engine; The End of a Swindler, 145. Mining Share Market, 148. The Week; Mining Shares in the East; The Reno Fire; The Impolicy of Labor Strickes and How to Prevent Them, 152. Notice of Recent Patents, 156.

ILLUSTRATIONS.—The Niles Improved Double Hoisting Engine, 145. Artesian Wells, 150-53. Stevenot's Free Gold Amalgamator, 153.

CORRESPONDENCE.—Letter from Arizona; Galvanizing Steam Boilers; Old Fort Miller and Surrouudings; From the Comstock, 146.

MECHANICAL PROGRESS.—Steam Engines to be Superseded; Grinding and Polishing Metal Surfaces by Hand; Bessemer Steel Anchors; Mechanical Giants; Metallic Packings, 147.

SCIENTIFIC PROGRESS.—Motion by Permanent Magnets; Ocean Currents; Electro-Chemical Action Under Pressure; American Dinosaurs; Electric Induction; Minute Causes which Affect Explosions; Nitrous Oxide Under Pressure; Experiments with Aneroid Barometers; A New Variety of Coal, 147.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 148.

MISCELLANEOUS.—On Artesian Wells, 150.

THE ENGINEER.—Locomotives Without Fire; Excavations and Foundations in Sand; Elevated Railways not Detrimental; New Tailings Dredger; The Great Hungarian Tunnel, 151.

USEFUL INFORMATION.—Cutting Glass; The Manufacture of Curtain Rings; A Vegetable Green for Confectioners; A New Writing Multiplier; Requirements of a Good Boiler Water; How to see the Wind; Cinder Wool, 151.

GOOD HEALTH.—Excessive Brain Work; Care of the Health; Constipation; Arsenic in Starch—A Singular Case of Poisoning; Poultices; Antiquated Sausages Poisonous, 151.

MINING SUMMARY from the various counties of California, Nevada, Idaho, Colorado and Utah, 149-56.

NEWS IN BRIEF on 156 and other pages

Business Announcements.

Miners Assay Office, W. H. Williscraft, Prescott, Arizona.
Assessment Notice—California and Oregon Land Co.
Delinquent Notice—Griffith Con. Mill and Mining Co.

The Week.

This week has seen the close of the 45th Congress and the adjournment of the Constitutional Convention. The former failing to finish its business, concerning important appropriations and other matters, has been summoned to extra session by Presidential message, and already the signs of partisan management and intrigues, for the control of either House, are plainly visible. The latter after sitting far beyond the time allowed to it, has given to us a new Constitution, asking that it be considered well by every voter before the time of the May election. The Chinese bill has been vetoed. But the news, with one or two local exceptions, has been received very quietly throughout the State, and there has been no trouble or disturbance as a result. The early part of the week was bright, dry and pleasant, but the end brought us the most drenching storm of the season. Here, over three inches of rain fell inside of 36 hours. We only regret that its abundance failed to reach the lower counties, Fresno, Kern, etc. Wednesday night it blew a strong gale from the southeast, the heaviest, it is said, known on the coast for 20 years. The ministerial question is still troubling France, and the cabinet is on the verge of another crisis, and will probably all resign. Reno has been laid in ashes by a terrible fire, and Silver City has also suffered in the same way. The women lawyers have carried their points, and the directors of the law school have been ordered to admit them as students to that institution.

In one district of Sheffield, Eng., there are 4,000 persons destitute, and 400 families actually starving.

Mining Shares in the East.

Operations in the shares of mining companies on this coast are beginning to assume very respectable proportions in some of the Eastern cities, the heaviest business in this line having thus far been transacted in New York, where the shares have been listed at the Mining Exchange and at the New York Stock Exchange. With a view of availing themselves of the active market that it is expected will open there for this class of securities, a good many of these companies have already procured their shares to be placed on these boards, the probabilities being that a like course of procedure will soon be followed by a great many others. It seems, indeed, quite probable that the quantities of these shares to be remitted to the Atlantic sea-board will hereafter be large, swelling into such proportions perhaps that we will find it convenient to estimate them as they do their ores in Colorado—by the cord. These consignments though large are not without precedent; we import about the same amount of playing cards from the East.

The mining shares so tendered the Eastern public represent properties of every grade—good, bad and indifferent. The list includes mines situated in California, Arizona, Nevada; some, in fact, in almost every one of our Pacific States and Territories. There are Washoe stocks, Bodie stocks, Eureka stocks—the fancies and the mines of merit all being called. Nor are these transactions confined to the stock boards; the bankers are beginning to deal in them, while numerous heavily-loaded private parties peddle them out, or sell as opportunity may offer, in lots to suit.

There is no reason why people in the East should not buy and sell these mining shares the same as is done on this coast. It is a business that in no case rests upon exact knowledge, or even upon very reliable information. Purchasers in Boston, Chicago and New York enjoy about the same facilities for posting themselves in regard to the condition, prospects and management of the mines that we do here. With the masses it is a chequered and hazardous business at best, more likely to bring them, in the long run, losses than gains, as the experience of outside dealers on this side of the continent fully establishes. There is no calculating the harm that our people have suffered from speculating in this class of so-called securities. It has caused the impoverishment—the utter financial ruin of thousands. It has led to more breaches of trust, defalcations and suicides than any other one thing, to say nothing of the demoralizing effects exerted upon those who have managed to make money by it.

But for all this it will go on. It will even grow and spread into communities that as yet have been comparatively free from it. When the poet wrote, "Hope springs eternal in the human breast," he meant, of course, the hope of making money by buying lottery tickets and speculating in public stocks. The propensity to make money through the instrumentality of chance seems innate and ineradicable. Reproof, admonition and argument are therefore unavailing to its repression. In this view of the matter, we expect to see these Eastern communities in due time properly entbused over our mining shares—to find in the cities there many prosperous brokers with each a numerous clientage—stock exchanges and a "booming market." The thing must have its day there as it has had here; for be it remarked, we on this side, are pretty well cured of this craze, and are about to advance our mining industries to a higher plane. There is a growing purpose among investors here to have done with stock speculations and embark in the business of mining in a practical and sensible way. The era of irresponsible managements, of well-paid but useless directors, and of merciless and misapplied assessments draws towards its close. Our people are not likely to be robbed through this gaudy machinery much longer. We have in our mines an inheritance of wealth such as never before fell to the lot of any people. All classes here are beginning to awaken to a consciousness of this fact, and it will not be long until we shall see a greatly increased activity in every branch of this industry. After many years of experiment and failure, of losses and mistakes, we have learned the business of mining for the precious metals pretty well. This knowledge has cost us dearly, but it will pay well in the end. We shall do our work with more economy and thoroughness and every way better hereafter, and do a great deal more of it too. There is going to be a good deal of money made at gold and silver mining on this coast from this time forward, and, as a general thing, it is going to be made in a more honest and legitimate way than has heretofore been the case.

The opportunities for employing money in this business are incomparable and boundless. There are here chances for the safe and profitable investment of all the surplus capital, not only of the Eastern States but of Europe, those who now invest having the benefit of our long experience, acquired skill and improvements introduced into the business. But, inviting as the field is to enterprise and capital, it is hardly to be expected that the opportunities it presents will just yet meet with entire appreciation abroad. Novices must be schooled to the business as we have been; must enjoy first the excitements of the stock bourse; try their hands at getting up corners, pools and deals; selling shares short and selling them long; traveling this road to the end, when it may be expected they will be ready to give their attention to and embark their means in actual and productive mining as we have done.

As yet, the majority of these Eastern purchasers seem inclined to pursue a cautious policy, showing a preference for the shares of improved dividend-paying properties of good standing and merit. This, for the time being, will no doubt be their best course, though it will not be long, once this preference is known, till mine owners will be found exerting themselves in a special way to bring their properties into this condition at the hazard of an early relapse into a non-productive state. Whatever is offered on the Eastern market, whether it be stocks or mines themselves, cannot be too closely scrutinized. As remarked by us last week, a multitude of irresponsible adventurers have lately made their way East loaded down with worthless shares and unproven mining claims with a view to disposing of them at almost any price. Much of this rubbish will be presented in a shape calculated to attract and deceive, being backed by glowing reports, newspaper articles, etc. But despite their goodly appearance there will be found concealed under these heaps of meal innumerable cats of the undomesticated species.

With so much that will be offered to Eastern investors of a dangerous kind, there will also be presented a great many properties worthy of acceptance; our object in this writing being to impress upon investors there the necessity that exists for discriminating between these respective offerings. In the gravel mines of California, both hydraulic and drift, should such be put on the Eastern market, investors may, as a general thing, embark their means with considerable safety, provided, of course, that these claims be opened and outfitted, supplied with water and otherwise favorably conditioned for active operations. Under other circumstances the most of these are properties to be avoided. It is the case, too, that vein mining in this State has, as a whole, been attended with satisfactory results. The failures that have here occurred, however, in this branch of mining are a standing protest against any relaxation of vigilance on the part of those who may contemplate engaging in the business. And so we might go on through a whole chapter, canvassing the inducements and dangers that everywhere attend mining investments without advancing our argument further than this: that our mineral fields present first rate opportunities for making as well as losing money, accordingly as they are turned to good or bad account. We have made here, as we will probably continue to make, great successes and great failures, though the latter, there is reason to believe, will be of less frequent occurrence hereafter than they have been in the past. In the future the chances of success will favor the operative miner rather than the speculator in stocks, the practical branch of the business being marked every year by less and less fluctuation, uncertainty and exposure to loss. To recapitulate a little, it will be seen that we have on this coast mineral resources almost without limit; toward the profitable utilization of these resources we have made great progress, having pretty well overcome the difficulties that for a long time beset the business. Our natural advantages aided by our acquired knowledge invite investments from abroad, all that is necessary to make mining here a success, being the observance of the same prudence, foresight and care that are considered indispensable in every other branch of business.

The Reno Fire.

Since the great fire in Virginia City, there has been no conflagration on the coast so sweeping and disastrous as that at Reno, Nevada, on Sunday last. It broke out at sunrise and raged all day till a late hour at night. One of those sweeping Washoe gales was blowing, and this combined with the scarcity of water, rendered it impossible to stop the work of destruction, till nearly the whole town was laid in ashes. Nearly 350 buildings, valued at from $750,000 to $1,000,000, were consumed. Of this amount, $200,000 only, is covered by insurance. Five lives are known to be lost so far—one woman and four men. Three of the latter were tramps. The fire is supposed to have originated in a woodpile near some frame dwellings. Once started, however, the high wind carried it with irresistible force from building to building, and so swiftly that the inhabitants had barely time to escape with their lives, saving, at the most, but a handful of their effects. Some of the heretofore well-to-do families in the city are reduced to poverty, and many of the poorer people have been left in an absolutely destitute condition. All the business portion of the town was destroyed, together with many dwellings. One hotel remained standing, and this together with such dwellings as had escaped, served as a refuge for the homeless and houseless people wandering in the streets.

Relief trains were promptly sent from Virginia, loaded with clothes and provisions. Further supplies were forwarded from this city, and on last reports the distress had been somewhat relieved. Steps were immediately taken to rebuild the burnt district, and many houses have already sprung up. Reno is now a suburb without a city, for this fire has swept away all those accumulations which distinguish it from the mining camp it was 10 years ago.

The Impolicy of Labor Strikes and How to Prevent Them.

The late striks in the Bodie district appears to have subsided, the mechanics and laborers receding from their demands and the employers carrying their points, as usually happens in similar cases. The most of the recent great strikes in England, New York and elsewhere have reached a like result; the workingmen, after refusing to comply with the terms offered by their employers as long as they could stand it, being at last forced to given in. An enlarged and dispassionate view of this subject reveals the fact that there is in the present condition of things much hardship involved on both sides. Take, for example, the case as presented in the Bodie district: Considering the remoteness of the locality, the cost of living, the rigors of the climate and the arduous and sometimes dangerous nature of the service required of the laborer, the wages demanded by him seem by no means excessive. On the other hand, there are here only two or three mines that are yielding the owners any present income; all the work and money expended upon the others is being done simply in the hope of striking something of value, but always at the imminent hazard of the whole being lost. Their value is merely prospective; the chances, if we consult past experience, being as ten to one that they will prove failures in the end. In attempting to develop these properties the owners, many of whom are persons of small means, run a great risk of loosing all the money they put in. In most cases it will be a long time anyhow before they will realize anything on their investments. Men working in and about these mines should consider these things, and not be too exorbitant in the matter of wages, nor otherwise exacting in their demands; remembering that but for the enterprise of these investors, attended so often by pecuniary loss, they would themselves be without these opportunities for earning even moderate wages.

And so, in looking over the world generally, while we find the laboring classes willing to work for a mere pittance, everywhere poor and often reduced to the verge of starvation, we find on the other hand financial embarrassment, ruin, bankruptcy, and prostrate trade, resulting from over-production in every branch of manufacture and department of business. At first sight it would look as if there were too many people in the world wanting employment for the work to be done. Yet such is not the case, the trouble being that there is too much conflict between the employer and employee, involving loss of time, energy and earnings on the part of the latter, and of skill, care and capital invested on the part of the former.

What is required is the adoption of some plan whereby these losses could all round be avoided; some method by which these classes would be able to consider and equitably adjust their differences without recourse to these labor combinations and strikes, which, while they produce so much bad feeling, result so disastrously to labor in the end. It seems to us that courts or boards of conciliation and arbitration, such as have in some places been introduced with excellent effect, might be more generally instituted for disposing of all questions arising between employers and employees in a speedy and inexpensive way. The findings of these boards, one of which might be established at every considerable mining camp or other labor center, would be likely to give general satisfaction, almost all men preferring to yield something even of their just claims to standing out for the last cent at the hazard of loosing valuable time and perpetuating a feeling of enmity and strife. We invite the attention of all parties concerned to this suggestion, satisfied that the plan proposed for settling their differences will, when they come to reflect upon it, appear so rational and practicable that they will at once set about organizing something of the kind.

Powder Blasts Here and in the East.—It is stated in a late number of the *Engineering and Mining Journal* that a blast of 12,000 pounds of powder had just been exploded in the quarry of the Glendon Iron Co., near Easton, Pa.; that paper going on to remark that this was probably the heaviest charge, not sub-aqueous, ever fired in the country; that it was an entire success, having effected an estimated displacement of 60,000 tons of rock, etc. While the above may be the largest blast ever set off in the Eastern States, much larger are frequently exploded in the gravel mines of California, where they sometimes burn five or six times as much powder as this at a single charge. Very recently the Reservoir Ditch Co. put off in their mine, at Sucker Flat, Yuba county, a blast of 50,000 pounds of Judson powder, a very powerful explosive, and by which between 200,000 and 300,000 cubic yards of gravel, some of it indurated into a hard cement, were so shattered that the most of it can be piped off under the heavy head of water here used. Occasionally even a greater amount of powder than this is exploded by the larger hydraulic mining companies, who find it economical to employ these heavy charges as doing more proportionate execution than small ones.

The value of the iron and steel exported from Philadelphia last year is put down at $3,000,000.

(Continued from page 150.)

qnske was experienced in this city and Oakland. Whether it had anything to do with the muddy water, is a qucstion. Dr. Saxe, from Santa Clara, ons of nur members, informs ms that soms walls in his vicinity that a year or two ago had flowed for a long time, suddsnly becsme muddy, and in a short time useless. His theory is, that ths force of the underground stream rushing to the bottom of the pipe to find an egress, collected ths pebbles aud larger gravsl in a pile around the pipe, and ths force of the water undsrmining the stratum abovc, it choked the pipe and prevented the flow of water.

An Unsuccessful Well.

In Septsmber, Morgsn & Co. bored a second well in ths hay, at their Millbrae station, the water in the bay bsing about 10 feet deep. Tho well was constructed in the same manner as their Dumbarton wcll; and after passing through mud, and the different strata of clay, gravel and sand, at 275 fect the auger penetrated a hard rock four feet, and no water having been obtained the well was abandoned, and the pipe taken up. Nnw draw a lino from point San Bruno (a hill on the main land 205 feet high), to point San Mateo (ths top of a small rocky hill projecting above the salt marsb), and the line passss east of the well, leaving a crssssnt-shaped bay to ths west. I think that ths well is on a submerged ridge, a continuation of the San Bruno mountains, which have an slevation of about 1,300 feet; and that San Mateo point is ths last low hill to ths south visibls on that ridge. The specimen marked *D*, of hard rock from this well, appears to bs hard cement gravel. The sams firm then commenced a third well at their Belmont station, which you will recollect is on a small island. This well, lately finished, is 358 fest deep, the last 15 fsst being sand, in which a good stream of water was obtainsd, thought to be better than at tbe Dumbarton station, which is hard; aud this is soft. At 308 feet, in ths Belmont wsll, passed through fragments of small shells one foot thick (see specimen *E*). A mils and a half south of the Belmont wsll, is one on the salt marsh, near the month of Redwood creek, sunk by McCollam & Co., on thsir former location, for curing Alaska codfish. This well is 7-inch bore, 202 feet deep, and flows a good stream of fresh water four feet abovs ths surface. These two last wells ars two or thres miles east of what I suppose to he thc submerged ridge.

Notk.—Mr. Morgan has furnished ms with the jaw of a sting ray, showing the peculiar formation of the mouth, which snables it to crush ths shell, and suck out ths oyster. He says that it is the only fish in this hay that destroys ths oyster. This jaw is from a small sized fish. The fence is mads of two by six-inch scantling, driven into the mud one foot apart, leaving six or eight feet above ths mud. The ray heing a flat round fish two feet or mors in diameter, and keeping near the bottom, cannot get through, and does not swim over the fence. Thsy are not to bs found now; but come again in the spring.

Diagram C

Is a cross section from San Francisco to Stockton and Milton, at the foothills of the Sierra Nevada. The observer is supposed to be looking north. The Pacific ocean and San Francisco are shown at ths left; then to ths east of San Francisco, the hay and Oakland; also, Redwood peak, 1,635 feet high; San Ramon valley, about 500 fest; Monts Diablo, 3,856 feet; Cave peak, 2,078 feet; the town of Livermore, 485 feet. Then ths delta of ths San Joaquin, 16 miles wids, which is overflowed at high tide; then comes Stockton, only 23 feet above the sea. (At a low stage of the river, ths tids rises and falls here two and one-half to three feet.) Now, at the intereection of Montgomery and Market streets, ths elsvation above the sea is 30 feet, or seven fest higher than Stockton. Milton, ths terminus of the Copperopolis railroad, elevation, 260 feet, is situated at the foothills of the Sierra Nevada.

Following are figures referred to in diagram *C*: 1, San Francisco; 2, Oakland; 3, Redwood peak, 1,635 feet; 4, San Ramon valley; 5, Mt. Diablo, 3,856 feet; 6, Livermore, 485 feet; 7, 7, 7, delta of the San Joaquin river; 8, Stockton well, 1,002 feet; 9, Milton, elevation 260 feet; 10, foothills of the Sierra Nevada; 11 to 12, level of the sea.

Tho line drawn east from San Francisco reprcsente the level of the sea. At San Francisco six wells are here shown: Three in the sandetone above the city hase, and three in the alluvial deposit below. These last are, the Stevens well, 144 feet deep; the Grand Hotel, 230 feet; and the well, 260 feet deep, at the Pacific Iron Works. The deepest part of the bay, just west of Yerba Buena island, is 144 feet.

At the railroad machine shop at Oakland point, a well, bored hy the company, is also shown. About 330 feet is passed through the alluvial soil without obtaining water. It now penetrated what is termed in the record, blue soapstone, 35 feet; then, soapstone, 18 feet; gravel, sand and clay, 4 feet; hlue soapstone, 16 feet. Most of the balance of the depth was alternate veins of soapstone and narrow seams of sand or gravel. At 454 feet a small quantity of water was obtained. At 550 feet, a hard, gray, arenaceous limestone was encountered; it was 20 feet thick. Below this limestone was 20 feet of very hard silicious rock. Lower down, the auger passed through different etrata of soapstone, elate, and other rocks, to the depth of 715 feet. No water having hesn obtained, the well was abandoned. I think that this well penetrated a submerged ridge from the hills east nf Oakland.

Stockton Well.

In tbe early part of 1858, the Stockton well was complsted. It was bored by the city and county authoritics (at a cost of $10,000), to test the practicability of obtaining a good stream of water; and, bsing a success, the county's interest was purchased by the city, and they now have a good supply of water for the inhabitants. My office at ths time, heing in the Court-house, within 100 fect of the well, enablsd mc to watch it closely, and I have a full recor.d of the well. The depth is 1,002 feet, through alluvial soil all of the distance. At the depth of 92 feet, a stratum of clay, sand and gravel, two fect thick, sligbtly impregnated with gold. At 340 fest, rsdwood log, in 14 feet of coarse sand, and water ascended to thres fest nf the surface. At 560 feet, in a stratum of fine, gray sand, 42 feet thick, obtained a stream of water, rising fivs feet abovs ths surface. At 913 fcet, entered stratum of clay and sand, 11 feet thick, and a large stream of water ross ssvsn feet above surface. At 1,000 feet (the last 11 fcet being clay, gravel and mica), entered two fset in sand, when a largs stream of water rose 11 feet above the surface of the plain and nine fest abovs ths city grads. Temperature of watsr, 77° Fahr.

Assisted by three gentlcmen, I carefully measured the water, and found ths discharge at the surface, through a nine-inch pips, to bs about 500,000 gallons in 24 hours. Ths water is charged with two gases, or, rather, tbe gases come up with the water, supposed by Dr. Trask and myself to he carhonic oxide and carbonic acid gas. I proposed to the Supervisors to elevate the watsr to the highest buildings hy mcans of the gas, and proved it ou a small scale, but they did not agres to it. I bottled soms of the gss, and kept it for six months; then opened the bottls and applied a light. It would not burn, but on turning the bottle over, it poured out like water and blazed up around the bottle.

With regard to the Stockton well, it is shown to be entirely in alluvial deposits to the depth of 1,000 feet. How much deeper this extends is not known. The pips to measure the hight of the water was 11 feet above the city grads; the water rose nine feet, and the gas, collected in the pips above the water, when a light was applisd to it, would burn with a flame about 18 inchee above the pips.

But it is evident from this and the small head that the water flowing from the well has, that its source is not in the Sierra Nevada, but is derived from the reservoirs in the different strata of sand or gravel in the basin between the foothills of the Coast range and Sierra Nevada. For it is well known that all of the emall streams and a portion of the larger streams eink as soon as they reach the deposits of large gravel in the plains at the base of the hills.

How, therefore, can we expect to obtain water from the Sierra Nevada under San Francisco at a depth of 200 or 300 feet, or even 1,000 feet? It is impossihle. All that we have obtaincd below the sea level is held in a small basin containing alluvial deposit.

Diagram D.

I will now call your attention to the enterprise of one of our citizens, Mr. J. B. Haggin, who has been engaged about two years in constructing an artesian well near the railroad, nine miles north of Sacramento, on the Norris grant. The elevation above the sea is about 150 feet, and about 8 or 10 miles west of the foothills.

In a letter to the Academy, dated May 3d, 1877, from Mr. D. C. Patten (who is boring the well), he says: We evidently passed through all surface strata at a depth of 864 feet; from this depth down to 1,090 feet is a conglomerate vein of soapstone, 226 feet in thickness, varying in character throughout, and coutaining one or two thin veins of lignite. Mr. Patten is keeping a record which will be furnished us when the wsll is finished.

Mr. Haggin informs ms that the well has reached a depth of 2,107 feet, and is now in qnicksand, with watsr rising to within 30 fest of surface; also gas sufficient to burn freely in a half-inch pipe. I think it very probahls that a stream of water will be obtained from ths Sierra Nevada, having ths best head of any well in the Stats; flowing, perhaps, 50 feet or mors abovs the surface. The well has cost nver $20,000.

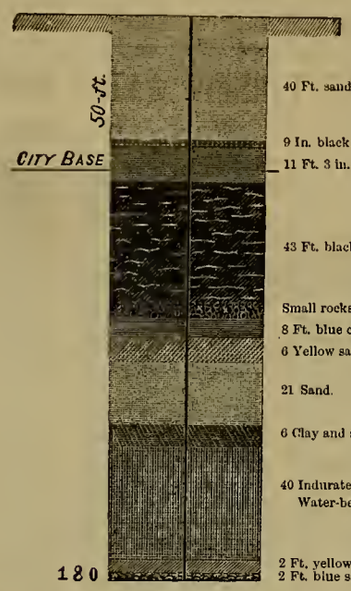
Ths specimens ssnt from this well called soapstone ars not soapstone, hut indurated clay.

Dr. W. Harknsss, who was at this wsll on Saturday, Dccember 14th, 1878, prssented ths Academy with soms sand obtained at the depth of 2,108 feet. Also stating that the water ross, as mentioned above, to 30 feet of the surface; but at times would suddsnly fall from 30 to 50 feet, and again suddsnly riss to its formsr lsvel. This will be further examined and reported.

In November, 1875, I received a report from Mr. F. C. Chass of a well that hc was boring at the Marysville woolen mills. The elevation of Marysvills above the sea is 67 feet. At 76 fest the auger cut the sids of a log 20 inches in diameter. At 195 fest, water so salt that stock would not drink it. At 285 fest, a small pisce of wood. At 306 feet, no supply of water yst.

I do not know to what depth this well was completed. Mr. Chase promised to write again, hut I havs not heard from him since.

I will now give a short account of one of the most remarkable artesian wells in ths United States; remarkahle for several reasons. First, the comparatively low depth at which a large stream of water was obtained; second, the head or force with which it comes to the surfacs, and the quantity discharged; third, the fact that the location is in a plain nearly level, and surrounded hy a lsvel country for many hundreds of miles; fourth, ths low temperature of the water; and fifth, that, with a single excsption, the boring was continned through ths rock all the way down, and was completed in 10 months. I have had a record of this well for several years.



New Artesian Well at the City Hall. Bore, 14 Inches. Scale, 50 ft. to 1 inch.

Stevenot's Free Gold Amalgamator.

The New City Hall Well.

Since this paper was written, the new well at the City Hall has heen completed to the depth of 180 feet, and work on it has been stopped for the present. I have, therefore, added it to diagram *A*; and also show it on a larger scale in diagram *E*. The location of the well is just east of the line of Hyde street, or three blocks east of Mr. Lyle's well (about 1,600 feet), which you perceive brings it on the east side of the basin formed between Gough and Leavenworth streets; but it is south of McAllister street or abont 4,000 feet south of California street. At the depth of 136 fset, ths indurated sand, or water-hsaring stratum, was reached. This is nnly 40 fset thick; when at the Lyle well it was 80 fest. It is therefore only capable of containing half ths amount of water. The bottom of this indurated sand is 150 fest hslow the bottom of ths 80 fsst in ths Lyls wsll, and if the water-bearing stratum nf the two wells are connected by a stream, the water in the City Hall well should raise considerably abovs ths surfaco, whereas it only just rsaches that point, or about 80 feet below the water lsvsl of ths three wells in diagram *B*. Theorstically, water rises to the level of its fountain head; hut practically it falls much short of it, owing to the friction and other causes.

The lower two fest of this well is said to bs in a hard, blue clay, containing small pieces of blus rock (specimens marked *F*). But it is probable that it is the bedrock cut fins hy the auger and bringing up some small pieces uncut. I gave some of ths rock to Prof. Price to examine, and he will report on them.

As was stated before, the last outcrop of tbe serpentins was traced to McAllister street. Ths next outcrop that I have seen is on Potrero street, about 5,000 feet sonthwesterly of the outcrop at McAllister strsst, and on the sams line of direction. This serpsntine may underlis the City Hall, the outcrop bsing about 1,700 feet west of it. But it will require further investigation.

In conclusion, I will say that if it is acceptable I will, at some futurs meeting of our section, give ths results of some of my observations during my surveys in different parts of the California basin, and the probable dspth of ths great inland ssa by which it was once covered.

Stevenot's Free Gold Amalgamator.

It is well known by svsry ouc who has had experience in quartz milling that a great deal of the fine gold contained in the pulverized gold ores is floated and carried off by water, on account of not getting in contact with ths quicksilver covering the copper plates of a quartz mill.

The following described amalgamator is intended for saving such fine gold, ths pulp bsing forcsd through a quicksilver bath, by which the fine gold is compelled to come in contact with the quicksilver. No machinery is required to givs ths pulp ths mechanical motion, the rotation being communicated to it by the currsnts of water hrought in contact by diffsrent pipes and under a certain amount of prssure, ths streams bsing rsgulated to suit the work by a stop-cock on each pipe.

Ths amalgamstor is composed of a shest-iron vat, which is 36 inches in diameter at ths top, 9 inches diamstar at ths bottom, and 36 inches deep. A pips four inches in diameter and seven feet long, with a hopper or funnel, 12 inches square at the top by 6 inches deep, servss to fsed ths ore in, by the top of ths funnel, being 24 inches highsr than the top of the vat. A one-inch water pipe insids of the feed pips, supplied hy a water tank with prssure, brings the gold and quieksilver in contact with such a shock as to compel the latter to taks hold of ths gold as the sand is forced through the quicksilver and raised to the surface of the hath in the vat. The vat or bowl being constantly full of water, the tailings therein are kept constantly stirred up and in motion by currents of water brought in by three-quarter-inch pipes, supplied by the water tank, the pressure producing the rotary motion in the vat. The tailings and surplus water run off hy the top dischargs or spout on the upper edge of the vat.

The pipes leading down into the vat, the water through which keep the contents stirred, are provided with stop-cocks, so as to produce a strong or light motion, which rsgulates the discharge of the sand. Plug or dischargs holes are made in the side of the vat, which are kept closed during the working and used to run down the heavier sand.

The level of the quicksilver hath in the amalgamator is indicatsd by the dotted lines as shown at *A* in the engraving. To clean-up the pipe in the bottom the vat is opened and the quicksilver will all run out. When a new charge of quicksilver is put in, the machine is ready to run again. It will only be necessary to renew the quicksilver once every two or three days, according to the richness of the ore. A 36-inch vat with a four-inch pipe is calculated to do the work for 10 stamps. This would make an extremely cheap amalgamator, very light for transportation, and having no machinery likely to get out of order.

The stream of water in the pipe which comee down throngh the feed tube takes the ore in said feed tuhe and throws it in fine particles on to the surface of the mercury hath so forcibly as to drive off any slimy particles which may he adhering to the gold, thus cleaning it and admitting of perfect amalgamation. Then as the particles of pulp are forced through the bath and rise in the vat, all the gold contained in it is amalgamated and the tailings flow off as described. The inventor, Mr. E. K. Stevenot, mining engineer, 322 Montgomery street, in this city, will furnish further information to those desiring it.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME St., N.E.Cor. Pine, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Penn, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

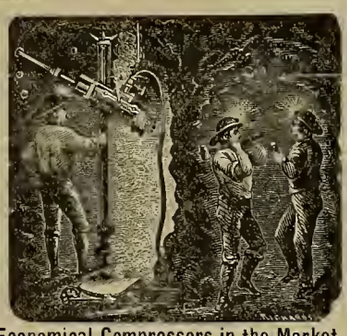
Address, P. O. BOX 2293, or 825 CAPP STREET, San Francisco, Cal.

When you come to the City, drop me a note in the Post-office, and I will find you.

Send for my New Illustrated Wheel Book for 1879. Prices greatly reduced and less than Eastern with freight. A large stock of all sizes always on hand. The only manufacturer of the Horizontal Penstock.

Ingersoll Rock Drills.



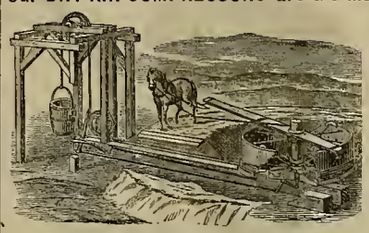
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

Room 10, Safe Deposit Building, San Francisco.

507 Mechanical Movements.

Every mechanic Should have a copy of Brown's 507 Mechanical Movements, illustrated and described. Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, $1, (post paid.

[Continued from page 149.]

moras. Late reports from the Reecue, at Silverado, confirm the report of a rich etrike. Tbe ore in the Needle mine ie increasing in value. It ie worked by two shifts.

REESE RIVER DISTRICT.

MANHATTAN.—*Reveille*, Mar. 1: The 517 west drift of the Curtis ehaft now carries a large ledge of very good ore, which seeme to improve in going up. The 660 stope also carriee the same ore on the west and below the 517 drift. The bottom ledge ie emaller, but containe fine ore. The 560 west drift having been run eome dietance ahead of the stope has been stopped. A chute, which ie being raised from the 600 weet drift to the 560, carries good ore. The 825 stope improves daily ae the ore body is opened out. The 825 east drift being quite a distance ahead of the ore chimney and the ventilation being bad, hae been stopped. Sinking the winze, in the North Star shaft, in the 600 west drift has been started, but it will be eome distance to the ledge.

WESTERN NYE.—Granteville *Sun*, Feb. 26: A diecovery bas been made in the lower south tunnel of the Alexander mine. This etrike is regarded as valuable becauee it ie helow the water line, and most clearly demonstratee the depth and permanency of the mine. At a depth of 244 ft a ledge of eulphuret ore has been discovered. The ledge has been prospected for seven ft, and as yet no eigns of a foot wall have been discovered. Tbe ore hitherto encountered in all the upper levels has been gray chloride and carbonate; at this point the ore body is changed to a heavy hlack eulphuret. The ore from thie ledge assays from $40 to $380 per ton.

COLORADO.

PHŒNIX-MAINE.—*Courier*, Feb. 28: Work at preeent on this property is confined to the two upper levels of the Coldstream ehaft where three parties of lesseee are at work. On the 60 level, Henry Stanton & Sone are working tbe east stope, that ehows an ore etreak from two to three inches thick that mills from 110 to 300 ouncee. On the eecond level, Cbris. Hanson & Co. are working a double shift drifting east, the hreast of their drift ehowing a etreak of ore that averagee ahout an iuch in thickness. Ben. Stanton & Co. are working the stope between the first and eecond levels, their ore being from two to six inchee thick but of a low grade—their last mill run dressed into one claes, giving but 65 ounces per ton. The company is erecting a California whim at this ehaft, ae the engine which was formerly here, bas been placed at the Phœnix shaft.

BACKSONE.—The main sbaft on thie lode, now 125 ft deep, is being eunk by Robert Woods & Co. under contract. Probably 40 ft farther will be reached before another level is started, wbicb will leave a block of ground for etoping between the first aud eecond levels 100 ft deep. Below the first level the sbaft ehows ore ite entire length, hut in placee carriee considerable iron. The bottom now showe about a dozen ore veins in the crevice, the largeet of which are from an iucb and a half to two inches in thicknese, compoeed of fine-grained galena.

THE Sunshine M. Co.'s mine, the Specie Payment, is producing as heavily ae ever. They are, however, piling up moet of the ore, their turbine wheel having given out several weeks ago. They bave their mill here full of ore, as well as enetom mill in Russell gulch, and will resume operations sbortly, ae they are expecting a new wheel on every train.

IDAHO.

SNAKE RIVER PLACERS.—*Statesman*, Feb. 20: Locatione of mining ground have been made from the confluence of the northern and eouthern branches of the great river, down to Glenn's ferry, 250 miles. Electro-plated machines are now being generally introduced. A Salt Lake company is located and working about five miles below Salmon Falls. It has a force of only four men at work, running day and night, with a result of $1.50 per hour for the two men engaged; the couples working alternately, each 12 hours. This company will put in another machine soon. A California company are putting in two machines. Charlee Lane is working two machines at Bonanza bar, 100 miles above the falls. Lane bas demonetrated that the high hars on the river pay about $4,000 per acre. All the hars tbat yield 25 or 30 colors to the pan pay from $35 to $40 per day. Some Salt Lake companies are at work on the south branch of the Snake river, about 40 or 50 miles above the mouth of that branch. About 120 miners' inches of water are required to work a machine of ordinary size. The price of the machines vary from $2,000 to $3,000. The gold ie worth about $21 per ounce; tbe gold being almoet pure. Only a small section of the river has yet been tested by the new procees; but it is known that the same character of gold is generally diffused throughout the gravel deposits along the entire length of the river.

BANNER.—Cor. *World*, Feb. 18: The boys at No. 2 are in 214 feet with their new tunnel, and this morning struck tbe porphyry, wbich lays on the foot wall of tbe ledge. The vein will be encountered to-day, and big things may be heard from this enterprise soon. A large stream of water is running from the face of tbe tunnel, which is indicative that all the old ehafts and stopes of Banner No. 1 are being drained.

UTAH.

NOTES.—Silver Reef *Miner*, Feb. 22: The Foundry and Iron mines have been purchased by Messrs. Campbell, Cullen & Co., tbe ore going from $20 to $60 in silver to the ton. The district ie known as the Silver Belt district. The foundry and minee will start up about the 1et of Marcb. Mr. Burgeee has put a force of men to work in his coal mine, and has considerable coal on the dump. Reports from tbe Salmon river mining country are more than favorable, and a good many Salt Lakere are preparing to locate there as soon ae the mining eeason opene. No unfavorable report eeems to have been made relative to the locality, and every prospect in course of development is turning out beyond the most eanguine expectatione. A doubt has existed as to tbe permanency of the mines, but so far the farther down tbe miners go the richer appears to be the ore. Tbe Stormont mill shut down for about 48 hours, to put in a set of new tanke. The Iron county excitement did not "pan out" worth a cent. The rock brought back ehowed no mineral. Tbe country rock wbcro the epecimens were obtained, is the variety generally known as the black volcanic, and bae never heen known to carry mineral of any kind.

SOME 20 persons are under indictment at Sprugfield for complicity in the whisky fraude. Many of them are the most prominent and wealthy citizene.

C. W. ANGELL, defaulting Secretary of the Pullman Palace Car Company, hae been eentenced to 10 years in the penitentiary.

A FIRE at Reno, on the 2d, destroyed 350 huildings, valued at $1,000,000. Five men and one woman perished in the flames.

WHEAT is coming forward at Portland in increased volume, and buyers willingly take all offered at current rates.

CHANNEL storms and snow drifts on the continent practically prevent postal communication with England.

THE rivers and creeks of southern Oregon which have connection with the ocean are filled with fine ealmon,

Arizona.

[Written for tbe PRESS.]

Notee of a Trip Through the Territory.

Ae we ehall leave this P. M. for California, or to go "inside" as they call it here, via Phenix and Maricopa Wells, we will make a few ohservatione ae to how we got here, what we have een and whom met.

Leaving San Francisco on Wedneeday, Jan. 8th, at 4 P. M., we sup at Lathrop and find oureelves at Mohave, on the desert of the same name, at breakfast. Thie ie a very bleak and desolate place, hut has coneiderable importance as the point of departure for the Lone Pine mining district and the country adjacent thereto. In this region the tree cactue ahounds and grows to a hight of twenty and thirty feet, throwing out its thick arms in a most grotesque way. It ie the Harleqnin of tree life. Ahout an hour hefore reaching Mohave we wind around the "Loop." Thie novelty in engineering ie 340 miles from San Francieco, ite length 3,795 feet, difference in elevatiou 78 feet. Between Caliente and Summit there are 17 tunnele, the longest of which is 1,300 feet. Leaving the desert we wind in and out through the Soledad pass aud through the San Fernando tunnel, which is as etraight as an arrow and 6,967 feet in length, down into the valley of San Fernando.

At Ravena, 51 miles north of Los Angeles, in the Soledad pass, ie located a mill for utilizing the cactus of this region hy working into paper. At a etation called Andrews, three milee eouth of Newhalle, ie located an oil well and a refinery. An attractive looking hotel ie also being built here, and we were informed that the etagee for Santa Barhara would eoon leave from thie point inetead of from Newhalle ae heretofore.

We had ahout an hour and a half at Loe Angelee for dinner, which was a great deal of time for the dinner provided. Leaving at ahout 3 P. M., we reached Yuma at 10 A. M., January 10th, three houre late. Fare from San Francisco to Yuma, $45, and $5 extra for eleeper. Breakfaeting at the "Colorado" we left on the "hnckhoard" at 11 A. M. for Preecott, via Castle Dome and Tyeour Welle; etage fare, $50.

As this route from Yuma to Preecott, for general travel, will soon be of the past we will note a few ohservatione concerning it. We arrived at Castle Dome ahout 5 P. M.; dietance from Yuma, 30 miles; one change of horees; time, eix houre. We forded the Gila soon after leaving Yuma, and the day'e ride was along the Colorado, through the meequit and greaeeweed, arrow-wood and palo verde, mostly over a eandy plain, monotonoue and nnintereeting, except for the changing views afforded hy the distant mountain rangee on both eidee of the river. We arrived at Tyeour on the morning of the 11th, nearly dead with the cold, which penetrated to the very marrow, notwithstanding our innumerable wrappings. Dietance from Castle Dome, 65 milee; time, 14 houre; two stagee of 30 and 35 miles. This line seeme to be hadly served. They run but two horeee to a etage, which, with the mails, express matter, coneiderable luggage aud three passeugers and driver is too much of a load over heavy roads for two horsee on long stages of 30 and 35 miles without change. Tysonr ie on the direct road from Ehrenherg, on the Colorado, to Prescott and Wickenherg, and is distant from the river 22 miles. Our course to thie point has been nearly north; here we change to the northeast. We reached Deeert etation, 28 miles from Tyeour, ahout 2 P. M., where we changed horses and lunched, arriving at Centennial station, 18 milee from Desert, ahout 7 P. M., making 46 miles for the day'e travel acrose the desert and over low ridgee, the monotony of the ride only hroken hy the storiee of adventure and exploit ae told hy "French Joe," a celehrated character in theee parts, whom we took up as an additional passenger at Tysour.

We arrived at Cave Creek at 4:30 A. M., after a night ride of 30 milee. We hardly had time to thaw out our etiffened fingers and swallow our miserable hreakfaet of fried hacon and heane hefore the "all ahoard" wae given for our last day's ride into Preecott. The road this day, mostly mountainous, leading acroee the ridges, up and down. Some 25 miles out from Prescott we struck into Kirkland valley, through which a sparkling stream of water runs, and cattle in considerahle numbere are grazing on either hand. Thie was the first hit of land we had eeen in 200 miles worth two hrass huttons. We dined at Dixon's etation at 2 P. M., where we got the only good meal on the road, and thie was good. Shortly after leaving Dixon's, fine timher begine to show itself upon the mountain sides. We have been gradually ascending all day and at 8 P. M. we reach Preecott (6,000 feet ahove the eea), 58 miles from Cave Creek; time, ahout 14 hours, and a total distance of 249 milee from Yuma; total time, 57 hours. We may eay here, in a general way, that traveling in the Territory is uncomfortable and expensive. Stage fares are from 20 to 25 cents a mile; meals, $1, and in the mountains $2.50 for keeping a horee over-night.

Upon arriving in Prescott we found the weather clear and cold, with eome snow. The Supreme Court and Legislature were hoth in seseion, which hrought together many of the representative men of the Territory. The Governor, General J. C. Fremont, and his family are very popular. He has hardly heen here long enough to have become personally known to many of hie widely ecattered conetituente, hut from hie early official connection with this coast, opening it upae it were for occupation hy the Americans, he has a strong hold upon the hearts of thie people. The Hon. Secretary, Captain Goeper, and the U. S. Marshal, Major Dake, hoth eerved with distinction in the war for the suppression of the rebellion, and are efficient in the discharge of their official dutiee and active in developing the material reeources of the Territory. Chief Juetice French, whose home is in Tuscon, has had a long experience upon the Bench, and is well and favorahly known throughout the Territory. A man of imposing presence and great dignity of character, Judge Porter, whose home is in Yuma, has heen seven years upon the Territorial Bench, and is well informed upon Territorial law, neuage and precedents and is in every way a valuable officer. Judge Chas. Sileut, the most recent appointment to the Bench of Arizona, ie from San Jose, California; is a clear headed lawyer aud an upright Judge. He has made a host of friends in the Territory hy introducing reforme in the administration of juetice, expediting the husineee of the court and reducing very materially its expensee.

Among the repreeentative men in the Legislature is the Hon. C. C. Bean, a memher of the council, who ie an old reeident in this part of the Territory and knows every road, trail, and etream in the Bradsbawe. He lovee the rugged mountain peaks and dark canyone and knowe them all hy name. He has traveled all over and through them and the country is like an old map to him. He ie largely engaged in mining and has done much to develop the mining intereete of the country and takes a broad view regarding the opening up of the country to capital and population.

In a future letter I may give your readers eome further information concerning the general resources and condition of Arizona, and then tell them my impreseione of ite mineral wealth.

W. H. S.

Prescott, A. T., Feh. 12th, 1879.

News in Brief.

NEVADA has a female hermit.

THERE ie 15 feet of snow in Schleswig.

IN 1878 the Parisiane ate 11,319 horses and mules.

COLUMBUS, Ohio, has heen five timee fired hy thievee.

THE new peueion bill places Jeff Davie on the penson liet.

REFORM in the tenement bouee eystem in New York, is propoeed.

A TREATY hetween Germany and Samoa was eigned January 24th.

ANOTHER earthquake was felt at Arequipa on the 19th ult. No damage.

YAKOOB KAHN is making friendly overturee to the Viceroy of India.

THE aggregate dehts of the Statee of the Union ie $345,197,000.

THE tax levy in Anaheim, the paet year, was only 60 cents on the $100.

DECISION will eoon he reached on the celehrated "mining dehrie" euit.

THERE hae heen a half-million-dollar run on a New Orleane eavinge hank.

THE Uniou Pacific, Kansas Pacific and Colorado Central have coneclidated.

A GERMAN company are about to establieh a heet sugar factory at Loe Angelee.

CANADA proteste againet a proposed parliamentary duty on American grain.

THE government troops have defeated the revolutioniets at Antioquia in Central America.

HOOS in Yolo county have recently heen afflicted with a dieease reeemhling diphtheria.

ONE HUNDRED AND SEVENTY-EIGHT arrests were made hy the police in Oakland, laet mouth.

MISSISSIPPI farmere are getting uneaey over the prospect of a wholesale departure of negroee for Kansas.

FEMALE etudents are to he admitted to Harvard College, hut subject to a eeparate governing board.

THE Potter committee report that Tilden carried Florida and Louieiana, hut wae counted out hy the Republicane.

THE Stockton *Independent* argues that San Joaquin farmere could not succesefully cultivate so emall a patch as 150 acres.

TWENTY-THREE sailors, on their way from Ferrcl, Spain, to epend the carnival in their native village, were capeized hy a equall and drowned.

SEVERAL tons of ice have heen put up at Mark Weet eprings, Sonoma county, this winter. The first time in the history of the county that it has heen attempted.

THE rehellion againet the Chineee government in Kashgar has heen completely crushed, and remnants of the defeated force are returning to Russian territory.

A CINCINNATI paper eaye a man named Dempsey leavee for California to engage a cargo of Chinese, which he will work as laborers on his air-line railroad contract.

A SPAN 110 feet long of the iron railroad hridge of the Chicago and Altoo road at Wilmiogton, Ill., gave way, precipitating three coal cars into the Kanakee river.

THE San Simeon whale etation gives employment to 21 men. Eleven whales have heen taken thie season, averaging 40 harrels of oil a piece. The oil is worth ahout $12 per harrel.

THE Workingmen will send a lecturer, accompanied by a Chinese leper, to follow on the track of Otis Gihson and his convert to Christianity, that the people of the East may see what Chinese immigration means.

Notices of Recent Patents.

Among the patents recently ohtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

ATTACHMENT FOR BOTTLE FASTENINOS.—S. Martinelli. Dated, Wateonville, Feh. 11th. This attachment is for the fasteninge to hottlee euch as are employed to hold the corke in place when effervereing liquids are confined in the hottlee. Theee fastenings coneist of a curved metal loop eo hinged at the eides of the hottle neck ae to ewing over the cork to retain it in place after tbe hottle is filled, and they are pulled to one side, when it ie desired to remove the cork. It ie often very difficult to remove theee fasteninge, ae they hecome imhedded in the cork hy the internal preesure. Thie invention consiete in the employment of a wire attachment to the link or fastening, so that one is enahled to overcome any etrain and remove the faetening at any time with very little effort.

CHAIR BRACE.—S. P. Sorensen, Rio Vieta. Thie iuvention relates to an improvement in chaire; the improvemente coueiet in providing peculiar hracee to hind the lege, eeate and arms together firmly, eo ae to etrengthen the chairs. A hinding rod is secured to each leg, tbe oppoeite ends of eaid rod meeting in a common plate on a holt in the center of the chair under tbe seat. A thumh ecrew on thie plate holde tbe plate in position and admite of ite being moved up the holt and tightening the rode, thus keeping the lege firmly in poeition. The hrace under the seat on which the holt carrying tbe center plate ie eecured, ie held in place by rode running from the arme of the chair, eo that theee rode are drawn tight hy the eame action of the screw that tightene the rode connecting with the lege. By thie meane the whole chair is firmly bound together.

[From the San Jose *Mercury* of January 17th.]

The Angora Robe and Glove Co.

One of the beet illustrations of what may be done to promote the growth of home industriee ie the work of the Angora Robe and Glove Company. The gentlemeu who eetahliehed this business, and wbo carried it to its present high degree of success, deserve the hearty thanks of every citizen of the Pacific Coast. Everything seemed against them at the start. Even their raw material was little thought of, and the processee of manufacture were almost entirely unknown. But they were not the men to be daunted by difficulties. Experiment after experiment was made, until at length the enterpriee was entirely succeeeful, and the grand results are now before us. Hardly a dwelling with any pretenelons but owes mucb of its elegance to their genius and skill. Tbe carriages that throng our streets, bearing the heauty and the chivalry of the city, are brilliant witb Angora robee and wrappings. The fur coat of the driver, hie well-fitting gloves, and even the whip with which he urgee along his fiery steeds, are manufactured by the Angora Robe and Glove Company.

As ie the case with most things worth baving, tbis enterprise hae been of elow and steady growth. When it was first started none of ite promoters expected to see it reach its present prosperity. They deeired to do wbat they could to establieh a new industry in tbe city, which they hoped might in time become succeseful and permanent; but their success has been mucb greater than they expected. They have now the largeet factory of tbe kind on tho coaet, and their goode are sold in every city on this eide of the Rocky mountains, and even in eome of the Eastern States. They have their own tannery, and have acquired tbe art of turning out more perfect skins than any other company io the world. They employ about 50 hands, more than half of whom are women, and tbeir annual products amount to nearly $50,000, and all has been done in a very few years.

And, beeidee thie, they bave created an unlimited demand for goat skins, and thus helped to diversify our agriculture, wbich is in iteelf a great advantage to tbe State. They buy all tbe skins that are sent to tbem, giving 30c. to 50c. for common skins, and 50c. to $1.50 for good fleece skine. The better tbe animal, and the greater tbe care taken of the skine, tbe higher tbe prices—a fact which all breeders should make a note of. Care should aleo be taken by coneignors to mark their own name carefully on eacb package of skins sent. By eo doing they will save the company much trouble, and possibly themselvee from actual loss.

The present officers of tbe Company are C. P. Bailey, President; Jackeon Lewie, Secretary; J. W. Hinds, Treasurer; and the Directore are all solid men of business. Mr. Bailey ie also one of tbe largeet breeders of thoroughbred and graded Angora goats on the coast, having about 4,000 animals on his farm at Battle Mountain, Nevada; Mr. Lewis is aleo a large owner and breeder of goats, and hoth gentlemen have a thorough acquaintance with the husinese, and will ultimately make it one of the moet valuable industriee of the State.

FRESH attractions are conetantly added to **Woodward's Gardens**, among which ie Prof. Gruher's great educator, the Zoographicon. Each departmcnt increases daily, and tbe Pavilion performauces are more popular than ever. All new novelties find a place at this wonderful reeort. Prices remain as usual.

EXAMINE the accelerative endowment plan, as origioated hy the Mutual Benefit Life Ineurance Co., of Newark, New Jersey. Assete, $30,533,429.94. Lewis C. Grover, President; L. Spencer Cohle, Vice-Preeident; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of ineured, 224 Sansome St., San Francieco.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinde of electrical and telegraphic apparatus to order. See ad. F. W. FOLLEN, 415 Market St., second floor, S. F.

And in accordance with law, and an order of the Board of Directors, made on the 21st day of January, 1879, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the Company, No. 330 Pine street, Room 48, San Francisco, California, on the 26th day of March, 1879, at the hour of one o'clock P. M. of said day, to pay said delinquent assessement thereon, together with costs of advertising and expenses of sale.

G. M. CONDEE, Secretary.

Office, Room 48, No. 330 Pine St., San Francisco, Cal.

Office Wide Awake Prospecting and Mining

Company.—No. 232 Sutter Street, San Francisco, Cal., February 1st, 1879. Location of works, Pickot-Post, Pinal County, Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the first day of February, 1879, an assessment (No. 6) of four cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 2, No. 232 Sutter Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fifth day of April, 1879, to pay the delinquent assessment, together with the cost of advertising and the expenses of sale. By order of the Board of Directors.

C. HILDEBRANDT, Secretary.

POSTPONEMENT.—The delinquent day of the above named assessment has been postponed until Tuesday, the First day of April, 1879, and the day of sale until Thursday, the First day of May, 1879, at the same hour and place. By order of the Board of Directors.

C. HILDEBRANDT, Secretary.

San Francisco, March 1st, 1879.

Summit Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the fourth day of February, A. D. 1879, an assessment (No. 7) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the eleventh (11th) day of March, A. D., 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Tuesday, the eighth day of April, A. D., 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

R. N. VAN BRUNT, Secretary.

Office, Room 6, No. 318 Pine Street San Francisco, Cal.

The California and Oregon Land Company.

—Location of principal place of business, San Francisco, California. Location of Works, State of Oregon.

Notice is hereby given, that at a meeting of the Board of Directors, held on the First day of March, A. D., 1879, an assessment (No. 2) of Forty Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, Room 5, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 10th day of April, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Saturday, the Tenth day of May, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. R. N. VAN BRUNT, Secretary.

Office, 318 Pine Street, Room 6, San Francisco, California.

The Large Circulation of the Min-

ING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana-British Columbia, and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

The "California Legal Record."

The ONLY WEEKLY containing all the decisions of the Supreme Court of California,

(The ONLY COMPLETE continuation of the S. F. *Law Journal.*)

Published every Saturday, in 8 vo. size—like the California Reports—contains EVERY DECISION of the Supreme Court, as fast as rendered, with a syllabus and statement of facts, and other important legal matter. The volumes commence on the first of October and April each, and have a full index for reference and binding.

REDUCED PRICE, only $5.50 per year, or $3 per volume of six months. Remit by Postal Order or Registered Letter, specifying what date or number to commence. Back numbers furnished. Sample numbers sent free. Address,

F. A. SCOFIELD & CO., Publishers and Prop's.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

SANDERSON BROS. & CO.'S

Best Refined Cast-Steel.

Warranted Most Superior for Drills, Hammers, Etc.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock and for sale

At No. 417 Market St., S. F., - H. D. Morris, Agent.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

SCREENS

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

PROMPT AND SUCCESSFUL.—*Messrs. Dewey & Co:*—Gentlemen: Your Circular letter, 12th inst., informing me of successful termination of my application for patent received. Please accept thanks for the prompt and successful manner in which you have managed this business Yours respectfully, J. H. CAVANAUGH.
Walla Walla, Dec. 24th.

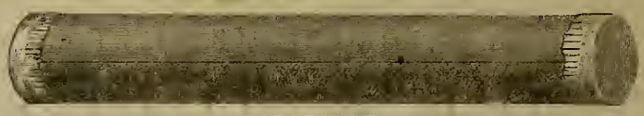
BERRY & PLACE.

Market St., Head of Front, San Francisco.

THE SAFETY POWDER COMPANY,

San Francisco, Cal.



CARTRIDGE.

GEN. W. S. ROSECRANS, President.

Fuse Lighter and Fuse.

COL. SAM'L O. GREGORY, Secretary.

Safety Cap and Fuse.

Electric Cap.

Safety Powder, Caps, Electric Caps, and Fuse Lighters.

Under a series of U. S. Patents, after long and carefully conducted experiments and thousands of tests, this Company is prepared to manufacture and supply, for Mining and Engineering Works, the above named articles at prices and on terms as favorable as articles of similar grades are now supplied in this market. Our Powders contain no Nitro-glycerine, no Nitroline, no Gun Cotton, no Fulminates, and are free from the unavoidable dangers in manufacturing transporting, handling and using of all high grade explosives which contain those elements.

Cold does not affect them. They cause no headaches or other inconveniences in handling, and the smoke from their explosion contains no poisoning or sickening vapors.

Their blasting force, with slight tamping, at least equals that of any Powders now used, but they admit and require strong tamping to bring out their immense and peculiar lifting power which follows their detonating work. They should be fired, therefore, by our

Safety Cap,

Which allows tamping without danger. They can be fired by any caps now employed in blasting, but the use of these is always dangerous with any Powder, and the loss of the throwing power resulting from lack of tamping renders it with our Powders doubly objectionable.

Our SAFETY CAPS have twice or thrice the force of triple Giant Caps. When set on fire they do not explode, but merely burn off, and are perfectly safe in transporting and in tamping.

In round tin boxes, 50 cents.

The Safety Fuse Lighter,

Cheap, handy and sure to light the Fuse upon the end of which it is fastened, only needs a trial to be appreciated by every miner who is up to "snuffs." 25 Cents per box; sent by mail.

Safety Fuse,

Equal to the best in the market, will be supplied at the lowest market prices.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED COPPER AMALGAMATING PLATES.

The BEST PROCESS yet discovered for SAVING FINE GOLD. Extensively used in Mines and Quartz Mills. Over FIVE HUNDRED ORDERS have been filled for these Plates.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and placer mining in various parts of the Pacific Coast. Over five hundred orders have been filled, and the demand is constantly increasing. A large number of these Plates were sent to Snake River mines, Idaho, last year, and a great many orders are being filled for them this season. Circulars containing full instructions for working these Plates sent with each order. Old Mining Plates bought or taken in exchange for new Silver Plated Plates, and full value allowed. Gold extracted from old Plates at a moderate cost by a new and economical process. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed.

Mining Men and the public generally are cautioned against unprincipled and irresponsible parties traveling through the country, endeavoring to secure orders for very inferior qualities of Silver Plated Mining Platee.

Boiler Explosions.—No. 2.

(Written for the PRESS by H. W. RICE.)

When steam engines were first introduced io Califoroia for furoishing motive power for threshing machines, it was thought by many that they could never be euccessfully used on account of danger from fire. The idea of having firo in a harvest field, where dry straw was scattered loosely about, or piled so oear that the smallest sparks could alight upoo it. Beeidcs, the sun poured down its heat almost intense eoough to make sufficient steam for the threshing work, and, undoubtedly, would do so if there was sufficicot moisture, and a way to receive and confine it. The danger from fire was all that was thought of as an obstacle to the success of stoam threshing engines. Danger from explosions was never discuesed or evon meotioned. No engiue was seut out witbout a competeot eogioeer to run it, and for a considerable time no explosioos took place. Engines at that time were not as large and powerful as at tbe prcsent day, and it was necessary to work them to their fullest capacity to do the work required; yet the work was performed, and no eugines exploded.

About four years after the first introduction of steam in our barvest fields an explosion occurred in Contra Costa county, near Pachoco. Probably there is oot a case on record wbere the destructive force of coufiued steam pressure was so dreadfully illustrated as it was ou that occacion. On the next day after the explosion we visited the place, for the sole object, if possible, of learning thc cause, and for sucb instruction as might be gained or obtained from a survey of the terrible wreck which was spread io such confusion over that large wheat field. At the time of our visit there was not a person preseot, aod a good opportunity preseoted itself to look carefully at what was to be seen, without hearing a word to excite or prejudice. Where the engine stood nothing was left but the ash-pan, which was flattened and bedded into the earth. The boiler was strong, and all parts being of nearly equal strength, no particular spot gave way, but it was literally torn into fragments. The largest piece was a boiler head holding the tubes—32 iu number—four feet eight inches long, aud two inches in diamter. This piece was thrown about 50 feet, and struck the eeparators, where the feeders usually stand. The steam dome, weigbing about 200 pounds, was lifted in the air and thrown ovcr the separator, and dropped about 400 feet from wbere it started. The truck wheels were tbrown in four different directions, and one of them we were not able to find. A span of horsee were standing near tbe separator, attached to a wagon loaded with bound wheat bundles. The horses were fully 40 feet from tbe engine. One of these horses was lifted into tbe air, carried over the load, and dropped about 15 feet behiud the wagon. Tbe wagon pole was broken and carried on top of the load, and parts of the harness were left on tbe way whicb marked the direction that was taken by the horse. We learned afterwards that a man was reclining under the wagon and a dog by his side was killed, while the man escaped uninjured. The engineer was thrown ahout 100 feet and, of course, was instautly killed. Tbe owner of the machine was struck by a piece of iron and crippled for life.

We afterwards heard a great many conflicting reports from different persons. It was said that tlie engineer made the remark in the morniug that he would "make steam with her or blow ber to —." The place he mentioned probably bas not a fit climate for our present style of machinery. This statement was contradicted, but having often heard the same or like expresieions, it offers a good opportunity to express disgust at recklessness or carelessness in any form, more especially when it endaogers the lives of ionocent persons who are obliged to work around these machines, besides beiug a very foolish piece of profanity.

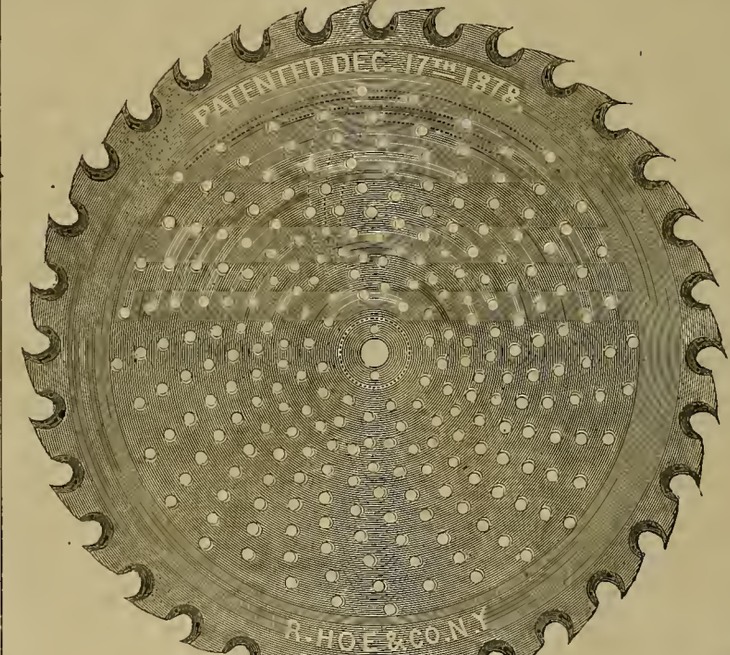
The most reliable information shows that the engineer was one who kept his engine carefully oiled and cleaned. The safety-valve was neatly ground to a perfect fit, no steam being allowed to blow off, and no part of tho boiler or engioe was allowed to lack tho least amount of water or eteam. It had been staoding for fully an hour with a fire of wood aod live coals, aod tbe steam gauge iodicated a pressure of 140 pouods. There was no water glass, but three compressioo gauge cocks were used to determine the amouot of water in the boiler. The engineer opened the throttle valve and directed a man to take bold of the fly-wbeel and start it off the ceoter. At the instaot it took eteam it exploded. Here is excellent opportunity to explaio the cause of ao explosion by either of two tbeories, as there were persons staodiog by who declare that the water was low, and others as pereistently maintaio that there wae fully two gauges. If the water was low aod the crowo sheet and top tubes were overbeated, it is easy to see that when the eogine valve moved and a cylinder full of steam was drawn out, tbe water would rise over the hot iron, and the explosion would be caused by the "spheroidal state of the water," a popular theory, which is fully described in old and reliable publicatioos which are in the reach of any person who wishes to become familiar with them. They should be carefully read by every engineer or eugine owner.

If there was plenty of water in the boiler, which was the more probable conclusiou, then the explosion was from another cause, whicb the nature of this case would indicate to be true. If a boiler which is perfectly tight has steam raised to a high pressure, and the fire is sufficient to keep up the pressure, no steam being allowed to blow off, and no water being allowed to be forced into it, it is supposed tbat the globules of water in the boiler come in contact with the heated surfaces, and, becoming heated, they move away, giving place to cooler ones. This slow circulation causes all the water in the boiler to be heated higher than would be required to make it into steam. If the boiler is left perfectly quiet, and allowed to cool off, no harm would come of it, but if the water becomes agitated, as by a shock or jar, to give it a quick motion, the globulee flash into steam instantly, and uo greater destruction could take place if it were filled with giant powder.

It is claimed that this can be effectually obviated by allowing the safety-valvc to blow gently, or by pumping in a little water quite ofteo. Io somo sawmills there is considerable timo that the engine is obliged to stand still while the saws aro being put io order, and it is positively ordered by owners that the safety-valve be always allowed to blow off while tbis is beiog done. If engineers of threshing engioes would make this a rule, undoubtedly a great many of the boilers would be saved which are now blowo up.

An Improvement in Circular Saws.

Our lumbermen aod wood-workers will be interested io the improvement in circular saws shown in the engraving on this page. The improvemeot is a simple one, and yet those wbo have tried it assure us that its working is most gratifying and effective. It is styled the ventilated or perforated saw, and is one of the many useful inventions of R. H. Hoe & Co. Its style of manufacture has an influence both upon the quality of the saw itself and upon its working, as may be learned from the following review of



THE VENTILATING OR PERFORATED CIRCULAR SAW.

the results obtained by perforating the blade in the manner shown in the engraving :

The manufacturers of circular saws tell us that all large circular saw plates warp badly in the process of hardening, varying from one to four or five inches from true. The tendency is to dish, because the periphery of the plate cools fastest, and has the same result as shrinking a tire on a wagon wheel. To obviate this difficulty the body of tbe plate is thickly perforated with circular boles. These allow of the contact of the cold oil and the escape of the gas generated by it and the hot steel, as freely throughout tbe body of the plate as at the peripbery. The whole plate will therefore shrink equally, and remain straight through the entire process of mauufacture. Platee frequently break while hardening, and many are broken while being drawn under the hammer, to counteract the buckle produced by hardening. A good working saw cannot be made from a plate that has been badly cast in hardening. Tbe unequal strain of the metal caused by hammering for the purpose of trueing a badly warped plate, is the principle cause of a saw's breaking while in use, or making a cut. The small circular holes, instead of weakening the plate (as unprofessionals would suppose), add materially to its stre ngth, and lessens its liability to break while working.

In the workiog of the saw it ie found that all the chip that escapes from the throats of the teeth and is driveu between the saw and timber, will fall into the holes and he carried out of the cut, thos relieving the plate from all friction and cooscquent heating. Furthermore, each beveled bole will act as a fan, causing a rapid curreot of air to flow through the body of the saw—air io motion abeorbs heat rapidly—and will tbus prevent the saw from beating. This method of ventilatiog large circulars is applicable to solid as well as chisel bit saws, and we shall be able to ruo mucb thinner saws than tbose oot so perforated.

It will be remembered that tbe chisel tootb circular saws are also the iovention of R. H. Hoe & Co. They have giveo wide satisfaction according to all accounts that we have seen. Tbese were introduced oo this coast by Tatum & Bowen, No. 3 Fremont street, S. F., aud the same firm is now introducing the perforated saw whicb we bave described. Tbe perforated saw has been used in the Puget Sound lumber district and the report is that its operatiou is moet satiefactory.

The Isthmus Canal Project.

Tbe old problem of a canal cutting tbe Isthmus of Darien is now assuming new life tbrough the persistent inquiry of tbe French. On another page in tbis issuc, will be found a brief summary of the results attained by the last body of French engineers sent out to study the feasibility of the eanal. Their report is being followed up by French writers wbo take up tbe resultant benefits of the canal and adorn them witb rosy colors. The latest of these views is that of the *Economiste Francaise*. This journal has been figuring the cailing time between different commercial centers, whicb court the Chinese trade, and the computations are fonnd to be vastly in favor of our Eastern seaboard over England. Our Eastern merchants and manufacturers are pushiug their Eoglish competitors close to the wall in many ports of the world, and they will make haste to avail themselves of any advantages whicb tbey may find in assailing the eastern coast of Asia with their merchandise.

Tbc French journal, to which we have alluded, gives statistics showing the actual differences in distances and time betwcen voyages from tbe English channel to Pacific and Chinese ports, and from New York to the same poiots. Tbe advantages are in favor of the latter, being to San Francisco, Callao, Valparaiso and Sandwicb Islands, four and a balf days, or from 3½% to 4⅜%, and 8½ days, or 7%, to Shanghai. If an isthmus canal be opened, tbe difference for sailing veseels would be 24 days, or from 33% to 51% from New York to the four places named, and 22½ days, or 28% to Shanghai. The average gain to New York vessels would be 2,000 miles, or 19 days over English and French competitors. Attention is then called to the iocreased use of steamers since the opening of the Suez canal. The same result would follow by the isthmus route. The difference then in favor of New York for steamers, which is now very emall, amounting to only one day, or from 1½% to 3%, would, with tbe canal, be, to San Francisco, 12 out of 29 days, 41%; Callao, 12 out of 21, or 57%; Valparaiso, 12 out of 27, or 44%; to the Sandwich Islands, 12 out of 35, or 34%—an advantage of 44% on the average for New York, simply doubling the commercial advantages to the United States with the Pacific.

It will he greatly to the glory of the Freuch engineers and capitalists if they succeed at Darien, wbere so many commercial powers, including our own government, have explored and turned back in dismay. Although, we should dislike, on general principles, to see any foreign nation win control of any artery of commerce which will he so important to tbis country as the isthmus caual, still if the project goes much longer by default by our inactivity, their cau be no cause for complaint. Perhaps it would be as well to have the French own the canal as auy other foreign power, and so long as we get the commercial benefit, perhaps we can afford to let the French raise tbe money and reap tbe glory.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Ens.

Douglas District, Wyoming.

EDITORS PRESS:—Douglas creek, in Douglas district, Carbon county, Wyoming Territory, is a beautiful stream running through the Medicine Bow mountain range. The Medicine Bow mountain forms a broad, elevated range, with a gradual easterly descent toward the Laramie plains. There is a narrow but beautiful and picturesque valley along the course of Douglas creek. This valley is very winding, and is over-topped by high peaks on either side. The average altitude is about 9,000 feet above the sea; the crest of the peaks about 10,000 feet, and the most elevated point probably 11,000 feet.

Kind of Rock.

The mass of the Medicine Bow range is gray gneiss and granite. The greater portion of the latter is red granite, its feldspar being red orthoclase. These metamorphic rocks have been penetrated by large masses of igneous rocks; and the great upheaval, displacement and scattering of the metamorphic rocks shows the igneous action to have been most intense. The action has been general throughout the range, though in some places we can still see evidence of stratification, but these localities are few. Any fossil forms must necessarily have been destroyed by the intense and wide-spread igneous action, rendering it impossible to give the age of the rock mass of which the range is composed.

At considerable depths below the surface the greater portion of the rock is greenstone (massive rock serpentine). This is shown by the development of the mines now being worked here, the Keystone and Florence; the wall rock of both these mines being composed of greenstone, occasionally passing into talc-schist.

Conclusions from Geological Formation.

Assuming that the now universally accepted theory of the formation and filling of fissures is correct (*i. e.*, the formation of fissures by earthquakes, caused by volcanic action, and the filling by chemical solution and infiltration from the interior, the solution being aided by steam and heated gases), we are led to believe that a great many fissures must have been formed in this range. And that a large amount of steam and heated gases must have resulted from the intense volcanic action, which would exist in the crevices long after the eruptive action had ceased, thus aiding in the solution of the metals and filling of the fissures.

The next inquiry will naturally be: "What metals are the material filling these fissures likely to contain?" Of the number and quantity of each it would be impossible to form an estimate, as many of the metals are found in veins which traverse all formation. I shall, therefore, confine myself to the probability of finding a single number of the group, viz., gold.

It does not require a very wise man to predict, and even prove, the existence of gold in this belt, as it has already been found in sufficient quantity to pay for its extraction in both the Keystone and Florence mines. Hence I will consider the probability of its being found in the veins and in considerable quantity. In this connection we must consider the influence of the country rock on the contents of lodes. While no general laws can be laid down under this head that will be applicable to all localities, yet experience has well established the fact, that for every mineral-bearing locality where the country rock is dissimilar a classification of such rock is admissible into what is called ore-carrier and non-carrier; this is especially true of gold-bearing districts, and in one district in the Hartz mountains a gold-bearing quartz vein is found running through gray and red gneiss. Now, this vein pays well during its continuance in the gray gneiss, but is almost barren in the red.

From personal experience I can state, that the country rock of all rich gold-bearing ledges that I ever saw (notably those of the South American mining company and Callao mining company in Guayana, Venezuela) was gray gneiss, the wall rock at considerable depths being greenstone in both instances. I am aware that good and paying gold-bearing veins have been found in a purely granite formation, but gray gneiss is regarded, and correctly so, as a far more favorable gold-bearing formation. I will here state that gneiss is a granite rock, but should not be confounded with a true granite. The chief distinction between them is that in gneiss the mica is aggregated into layers, giving to the rock lines of cleavage; while in the true granite the mica is irregularly disseminated through the mass and possesses therefore no lines of fracture.

One of the veins before alluded to, viz., that of the Callao mining company, has a maximum width of nine feet, pinching out in places to three feet, the average being about six feet. Now, this district (Douglas creek) has been subjected to more intense igneous action than that of Callao. The country rock is essentially the same in both districts. It is not unreasonable, therefore, to predict the existence of as large, or even larger, gold-bearing veins in the former as in the latter.

A Good Field for Prospectors.

But little prospecting has been done in this range, yet I know of no better field, and for two reasons: 1. On account of the good natural facilities the district offers for treating all classes of ore. 2. The excellent wagon road between Laramie City, a pleasant city situated on the Union Pacific railroad, and the range.

The entire range is covered with a thick growth of pine; the trees have an average diameter of about one foot. This timber makes an excellent fuel, and is also good mining timber; the only expense to be incurred would be that of cutting and delivering.

Douglas creek furnishes an abundant supply of water for all purposes, both winter and summer. So that the question of a sufficient supply of fuel and water for metallurgical purposes is here very nicely solved.

A tri-weekly stage coach runs between Laramie City and the town of Douglas. The latter is a mining town of about 200 inhabitants, situated in the range, and about 12 miles from its eastern slope. The road is through the Laramie plains for a distance of 33 miles; then ascending the eastern slope of the range it leads through the most level portion of the same for a distance of 12 miles, when Douglas is reached. Grading has been done where it was found necessary, so that good facilities are offered for travel and the transportation of heavy machinery between the range and the Union Pacific railroad. J. G. MURPHY, E. M.

The Industries of Inyo County.

EDITORS PRESS:—This region should, geographically, belong to Nevada, lying, as it does, east of the Sierra Nevada mountains. Our supplies from San Francisco are shipped either via. Carson or the southern route, via. Mohave. By either route, freight is about five cents per pound, and thousands of tons are shipped yearly to these mining districts and farming settlements. From Borden, Fresno county, the distance nearly due east, across the Sierras, according to survey made last summer by Mr. Sherwin, is 90 miles to Lake district, a new mining district formed last year. There is a good wagon road from Borden, or Madeira, to the saw mills at Fresno Flats, distance, 50 miles; the other 40 miles, there is only a dim, rough trail. It is estimated that $50,000 would build a wagon road through to Lake district. This district (altitude about 9,000 feet above sea level) is on the eastern slope of the Sierra Nevada range. Running parallel with the Sierra is another grand range called the Inyo, or White mountains, where peaks of 12,000 feet and upwards may be seen. Lying between these two romantic ranges is Owens valley, which is over 100 miles long from Lake district to Owens lake. Owens river heads in the vicinity of Lake district, and empties into Owens lake, while the San Joaquin heads a short distance from the other, but meanders to the western slope of the Sierras.

Mines and Farms.

Mono lake, the "Dead sea of the West," is only a few miles from Lake district, and the celebrated Bodie mines are still north of Mono. Imagine, now, that you are looking south from this elevated region and you will take in wild, romantic sceneries, especially along the Sierras from Mono to Owens lake. But, unless there is "money in it," what do we care for the grand and sublime in nature! Well, then let us scamper south along the Inyo range and detached hills, and we will strike some rich mining districts. There are Blind Springs (Benton), Indian district, Montgomery, Indian Queen, Bellville, Columbus, Silver Peak, Golden Wedges, Johnson mines, Lida Valley, Eclipse, Darwin, Cerro Gordo, Coso mines, etc. Strike again across the valley and run north along the eastern slope of the Sierra range, and you will run into Alahama, Kearsarge, Silver Sprout, Fish Springs mines, Bishop Creek mines, French district, Minnietta, Laurel, Lake Prescott, Dunherhurgh, etc. Judging from present indications we are "almost persuaded" that the mineral resources of this big country is inexhaustible, and that within a short time the population will increase a hundredfold, when streams of hullion will be continuously rushing to your city.

We will start again at Lake district, which overlooks a large valley called

Long Valley,

About 15 miles long and several miles wide. On account of its altitude, about 7,000 feet above sea level, it is not a grain-producing valley, but an excellent summer range for stock, grass and water being abundant. Thousands of horses, cattle, sheep and hogs are driven early every summer into this valley from the various settlements south, and late in the fall are driven back again by their owners. Owens river runs through Long valley. About 100 miles south of this valley is

Round Valley,

Which is six miles long and three miles wide. This is a fine valley, under a high state of cultivation. Wheat, oats, barley, corn, potatoes, and all kinds of vegetables grow well here. Although the altitude is between 4,000 and 5,000 feet above sea level, good crops have been raised every year (no failure yet) since 1865, which was the first year of farming in this locality. This valley lies at the base of the Sierras, and is well watered by three large creeks, which are sufficient for irrigating purposes. Two or three miles farther is

Pleasant Valley,

Where several farms are yielding good crops. Still southeast four or five miles is the thriving settlement of Bishop Creek. Four stores, two schoolhouses, church, two or three hotels, a number of saloons, two flouring mills, one brewery and malt house, shoemakers, blacksmith shops, etc., flourish here.

About six miles south of Bishop Creek is the "Watson place," where grain and alfalfa do well and considerable fruit is raised. A vineyard of 15 acres, producing excellent grapes, may be seen here.

Still south seven miles is the Big Pine settlement, where large crops of the cereals, alfalfa, etc., are raised.

On a "bench," nestled at the base of the Sierras and almost encircled by hills, is a fertile little valley of a few hundred acres, where fruit in great profusion is grown by Bell and Baker.

Fish Springs, seven miles from Big Pine, is another farming settlement, and from there to Independence there is more or less farming done.

Independence

Is the county seat of Inyo, where a weekly paper (*Inyo Independent*) is published, which has for seven or eight years disseminated valuable information respecting this region. Camp Independence (the "Fort," two miles north of town,) is in latitude 36° 50′, altitude 4,598 feet above sea level.

From Independence, south, to Lone Pine (16 miles) there is also considerable farming. Lone Pine is quite a town, where the southern mining camps of this county get their supplies. A few miles south of Lone Pine is Owens lake. From the lake, in fact from Lone Pine, the country is a desert waste to Mohave, the nearest railroad point, over which the Cerro Gordo Freighting Company navigate their "prairie schooners."

All the foregoing settlements lie west of the river (Owens) and the thousands of acres under cultivation are entirely irrigated by the large, purling streams issuing from the canyons of the Sierras. Very few streams flow from the White mountains, hence the comparative scarcity of the arable land along their base. However, considerable desert land is being reclaimed east of the river, water for irrigating purposes is taken out of that large stream. Several miles of ditches have already been dug by Col. Alexander, Owens, Collins and others who raised a crop last year. It is stated that the land is very productive, providing an abundance of water is applied.

More anon, respecting our climate, soil, its products, etc. T. E. J.

Owens Valley, Inyo Co., Cal.

Atomic Silver — Electrical Metallurgy.

EDITORS PRESS:—The following extracts are from one of many letters I receive on the amalgamation of metals, and as this subject is of universal interest I answer it through the PRESS:

Almarin B. Paul—DEAR SIR: I received with much interest your article entitled "Rebellious Miners," published in SCIENTIFIC PRESS for November.

1. If the atomic doctrine be true of gold, is it not equally true of silver?

2. Does not our silver ores as a general thing contain a goodly percentage of metallic silver?

3. It occurred to me while reading your article that our scientific men ought to experiment more largely with electricity in reducing and saving the precious metals. Our best writers on chemistry now admit that all chemical action depends on electrical action; in other words, that electricity is the intelligent agent.

4 What are the results of your experiments in this direction? Electricity is the coming power and should be carefully looked after by mining men.—A. W., Vestal, Montana.

Upon these points I comment as follows:

1. We cannot apply the same rule to silver as to gold, though both are precious metals; and for the reason that while gold is a simple, silver, to a great extent, is a compound, in other words, not universally in a metallic condition. The great value in the Comstock ores (outside of gold) is in metallic silver, and there is no reason why much of it is not in an atomic condition, though I do not think as universally so as gold. Although I worked Comstock ores for over six years, I never investigated the atomic question, as relates to silver, as I have since, with gold; and for good reasons it takes a vast number of atoms of silver to make a dollar, while a dollar is easily lost or saved if gold; and besides, the percentage gained in working silver, is so vastly ahead of that gained by the barbarous way of working our gold ores.

2. By experiments, I have satisfied myself that there is, in all ores, a much larger percentage of metallic silver than is usually credited to be, and besides there is a great deal of ore considered "rebellious" silver ore that can be worked in consequence of its large per cent. of metallic silver, to a much greater profit without fire than with it; this I apply more particularly to lower grade silver ore. There is too general an opinion that because an ore may carry a large per cent. of silver, that the only successful way to treat it, is to chloridize. I admit a better per cent. may be obtained, but will not admit that in all ores it is always the best way or the most profitable. In this age, we work more for profit than per cent., glory or science. One reason there is such a general resort to the roasting of silver ore is, some carry the "baser" metals, as lead, zinc, antimony or copper, and as all must be worked "like they work the Comstock," where the ores are entirely dissimilar, the result is they produce very base bullion, besides vitiating the mercury, and making, in consequence, a heavy loss of mercury and silver. To avoid this "fouling" and baseness of bullion, they say the ores must be roasted. Thus far, they are right, but by a change of operation, and not "work like the Comstock," all the expense of roasting might be avoided, and as good result, with merchantable bullion obtained. If our millmen do not know how to accomplish this, I do, and others as well as myself.

3. Now as to the electrical feature as applied to amalgamating the precious metals. I have expended 10 years on this very question, and have accomplished much, and with one exception—a treatment for the separating cheaply, of the precious metals from base bullion. I have concentrated the good points of these experiments all into my "Dry Amalgamating Barrel Process." You will see in my last pamphlet, page 9, that I say—

Although I have well considered the science of its metallurgical features, its introduction here is of minor importance. This is a practical age; man's aim is wealth rather than science. I therefore present it in a practical shape, and for the present will only attempt to prove my statement by *bars of bullion;* but here I must say, that the process, in a scientific sense, is in perfect accord with the effectual laws of chemical and *electrical science*, all of which, in due time, will be as much appreciated by the scientific, as by the practical miner, who only scans his bullion as a test of merit.

Again, on page 5 I say—

I adopt, therefore, dry reduction, and add to it dry amalgamation, *under heat of electrical action, which in all nature is life*, thus producing amalgamation by *attraction* as well as compulsion.

I first called this system the "electric process," as the amalgamation is based on electrical science, but subsequently dropped the electric part, for the reason I found it was making pecuniary headway backward, this talking about electrical metallurgy, as too many mining men get frightened when they are asked to touch anything with some new scientific idea in it, just as if the art of handling precious metals was to stand still while the world was advancing in everything else.

At the same time I dropped the talk I did not drop the merits or give any further explanation, and now could convey considerable more on electrical metallurgy than I propose to do. What is the use of parading any new scientific fact for solid-headed miners? They want the bullion—not science. The more one seeks to give scientific solutions for practical results the less value is given to any new process or discovery, no matter what it is. I might also add, what is the use of expending time and money on experiments? There is no reward for it. In fact one actually injures his reputation as a sensible business man by advancing new principles, no matter how great the merit.

4. As to the progress and results I have made by my radical treatment of ores, I will answer thus:

1st. I have determined that what has been deemed a myth of alchemistical science to be a *practical* fact—viz, that there is such a thing as "philosophical mercury" (as the alchemist called it). In practical wording, that mercury can be placed in such a condition as to have affinity only for gold and silver. In other words, that I can work ores containing gold, silver, lead, antimony, zinc, copper or arsenic, as a whole or singly, with the precious metals, and amalgamate *only* gold and silver, and produce bullion finer than coin, and oftener above 950·1000 fine than under it, and will prove it can be done on a scale of 100 tons a day as easily as 100 pounds.

2d. That the large body of silver ores now put through the process of roasting can be more profitably worked without it and all bullion be free of base, or, rather, 950·1000 fine.

3d. That by the disintegration of ores and chemical applications, I can generate, in a *practical amalgamating machine*, so much electricity as to defy the strength of the strongest man—not only that, but be dangerous to handle.

4th. That I will amalgamate gold so fine that paper can be gilded with it.

5th. That there is no such thing as gold being in any other condition than metallic—in other words, that gold is a simple.

6th. Taking ores from any of the leading gold mines of California that the best mills, working stamps, copper plates and blankets, do not get, on an average, 40% of the full value of the ore.

7th. That the majority of mills of California working as above, do not average one-third the value of the ores, and that the great bulk of the gold lost is atomic gold, and gold so fine that paper can be gilded with it in its natural state.

I make the above declarations as important and practically deduced facts for such of the mining community who can appreciate advancement. Now, some may say if I can do all this, I ought to be a very rich man—that all I should want would be bags to put the gold in. But such is not the case. My mind has been too many years absorbed (very foolish in me for my own interests, I must admit,) in these experiments, and so much so that I forgot how to make money, and only remembered how to spend it. I propose, however, to change this programme, and now will endeavor to turn experience to some purpose. Really, Mr. Editor, I must beg pardon for making so long and free an answer to so short a letter, but my ideas run away with my pen. More anon. Yours,

ALMARIN B. PAUL.

San Francisco, March 1st, 1879.

MECHANICAL PROGRESS.

A New Iron Car.

Since the first railroad became a practical success efforts have been made with unusually poor results to make good cars of the same material as the tracks. Two classes of men have been experimenting. One composed of engineers, who have not made sufficient allowance for the strains developed in practical use, such, for instance, as an occasional collision, and went to the extreme of light construction; the other class of practical car builders started on the basis of their experience in wood-working, and not only used too much iron, making their cars heavy and costly, but used it in forms not well calculated to give good results, because the material was not applied in a way to secure its full strength. A couple of Buffalo gentlemen, who combine both energetic and practical training, have recently invented and patented an iron car which is expected to strike the happy mean. The inventors are Charles H. Kellogg, engineer of the Kellogg bridge works, and Mr. John W. Seaver, mechanical engineer of the same establishment. Several trial cars are now being constructed for the Buffalo & Southwestern railway so that the results of their practical use will soon be known. These gentlemen claim that if an iron car can be made strong enough to cut through any wooden car in a collision, and to keep its shape even when thrown from the track, it will last practically forever, that is, of course, excepting the necessary renewal of wearing parts. By their improved construction platform cars can be built for $500, and they will make contracts at these figures. The improved car uses, however, a patent semi-elliptic spring, costing about $50, which would make the two cost just the same as if built on the old plan.

One novelty in construction is the entire absence of any truss rods under the frame, all the iron that would have been used in them being added in the form of two additional longitudinal sills. The truss rods were good enough in resisting dead weight, but, in case of accident, the frame would buckle sideways or upward and the rods gave not a bit of resistance. As now built, the frame has six sills of channel iron, giving great stiffness in all directions, while at the same time, making the weight of iron used the minimum. Every piece is riveted in its place and no dependence is placed on bolts and nuts. A large factor of safety, seven, is allowed in estimates of strength of the trucks, while five is the factor of the box frame. In a form of coal car now being manufactured, every part is iron or steel, even to the floor, sides and cross-bars on the brakes. This iron floor of riveted plates adds largely to the strength, but no allowance is made for that in the estimates. The inventors make a point of the arrangement of the swing motion and springs, a special patent covering that construction. The arrangement is such that the springs cannot be overloaded, as after dropping to a certain point, or in case of breakage, the weight is taken up by the bearings and the springs entirely relieved. In going around curves the body swings in a sort of parallel motion from the spring hangings and settles easily back on the bearings when the curve is passed. In every part of the work rolled iron of the form best adapted to meet the peculiar strains of the situation are used, and the result is a car weighing but eight tons that will carry 20 as easily as the old wooded cars can get along with 12.

We clip the above from the Buffalo *Courier*. In regard to the wear of iron cars heretofore and the prejudice which exists against them, a correspondent of the *Railroad Gazette* says: Some 20 years ago the New York Central & Hudson River Railroad Company added to their rolling stock 500 iron box cars, the floor framing being of six sills of riveted channels, and the box of 2 × 2 × ¼ angle irons, covered with iron 1-10 of an inch thick. The bodies were all iron, excepting the floor and a lining some three feet high. These cars, after 20 years' use, are to be found upon the main line and its connections, in apparently as good condition as when new. Occasionally there is one with a small patch in the side where the iron has rusted through. Notwithstanding this good service, a number of minor officials and employees of this road persist in condemning iron cars in general, and invariably say: "Our company built 500 of them 20 years ago, and have not built any since; therefore they are good for nothing." Now let us ask the reason thereof.

If these cars, built at a date when the knowledge of iron construction was in its infancy, will pass through 20 years of service unharmed, is it not safe to conclude that, with the improved shapes of iron at command, together with the experience developed by the greatly increased use of iron in bridges, buildings, etc., where it is superseding wood daily, that a car possessing the essential requirements of good rolling stock, viz., lightness, strength and durability, with easy access to wearing parts, and lastly, and probably one of the most important qualities, cheapness of manufacture, may be produced? Possibly the true reason for this animosity to iron cars in general by these gentlemen is that, as a class, they are men unskilled in the construction of iron, their experience being confined to wood, and that it is but natural they should give preference to a form of building with which they are familiar, and condemn any innovation in their branch of work that would necessitate either their learning what would be comparatively a new profession, or being superseded by men who possess such knowledge.

Composite Ships.

Notwithstanding that the mixed construction of vessels has been tested and found wanting in the elements of strength and durability, both by the government and by individual shipowners, still there are those who adhere to its fortunes, and advocate the adoption of this type of construction as adapted to the general want. There are four prominent objections to composite vessels: 1st. Wood and iron do not work well together, unless the iron is galvanized, and this would make the vessel too costly for general service. 2d. The frame should be stronger than the planking. There is so much of common sense in this to a practical mind, that we need not pause to discuss the question. This required strength can only be obtained by increasing the number of frames in the vessel, or making them much larger, and indeed both are a necessity. 3d. The security of the butts of the planking is insufficient, especially at the wood ends, where a nut cannot be put on the end of the screw bolt in the vicinity of the deadwood. This leaves the wood ends insecurely fastened. The butts elsewhere also have no solidity of fastening. The plate extending from frame to frame to receive the butt is a sham at best. The frames should be sufficiently near each other to become the recipients of a scarph nib on each frame, and the planking should be scarphed flatwise, or, in the thickness of the plank; in a 4-inch plank, the inside nib may be 1½ inches, and the outside nib, 2½ inches; the inner nib should be tight, and the outer one calked, showing only one butt, the scarph extending across both frames, and receiving fastening through both frames. The fourth objection is in the small fastenings, the bolts are too small to hold the planking solid for calking. The points of the holts do not fill the holes in the frames, and cannot be made to fit unless the points are of reduced size, and then they would be of insufficient strength. The calking of composite vessels is of the boat calking type, mere chintzing compared to the solid calking of a wooden vessel. In the very nature of the materials it is quite impossible to have drift sufficient to make the fastening tight in the wooden plank and loose in the iron frame, and yet have solid work. When composite vessels are built, the planking should be sufficiently thick to receive edge bolting between alternate frames. As a general rule, however, ship-owners have been more anxious to show that the composite is the cheaper than that they are the better vessel. Ship-owners, as well as underwriters, will learn by experience, if in no other way, that the best ship is the cheapest.—*The American Ship.*

The Great Government Testing Machine.

The great testing machine designed by Mr. Albert Emery, for the United States Commissioners for testing iron and steel, which has been in process of construction for three years past at the Watertown (Mass.) Arsenal, is now completed. Some experimental tests made with it in the presence of the Commissioners are thus described by the Boston *Traveler:*

The merit of this new testing machine lies in its great power united with its mathematical accuracy. In illustration of this, a few of the interesting results it has reached in the course of the recent experiments may be cited. A five inch bar of iron was pulled apart, and the strain registered in doing it was 772,000 pounds. To attest its minute exactness, a horse hair was next submitted to the strain, and it yielded to a registered force of two pounds. Again, a pine blocks of four inches thickness and two feet in length was taken and pressed into a board of two inches thickness. Then, to again ascertain refinement of accuracy, a hen's egg was taken and inclosed in plaster of Paris, with two small holes in each end, and, the pressure being applied, the contents were forced out of these apertures at a strain of 25 pounds, and such is the command over the action of the machine that the pressure was stopped in an instant, and the yolk ceased to be expelled, the shell of the egg remaining unbroken. A nut was also cracked by the machine without crushing the kernel. No such nicety of regulated pressure, combined with such an enormous range of power and absolutely exact registration of the strain exerted, has ever before been attained.

PROGRESS OF STEAM ENGINE ECONOMY.—With Smeaton's early Newcomen engines the consumption of coal was 29.76 lbs. per hour per horse power. Afterwards, as improved, 17.6 lbs. In 1811 the Cornish pumping engine required 10.87 lbs. per hour per horse power; in 1842 the improvements had reduced it to 2.90 lbs. In 1863 the best marine engines consumed 4 lbs. of coal per hour per horse power, but in 1872 only 2.11 lbs. were required.

THE most fatal disease that threatens the vitality of many of our oldest and largest machine establishments is *Conservatism.* When a concern settles down to running on its accumulated reputation, without an effort to improve its patterns, processes or style of work, the disease will surely enfeeble it, while its enterprising rivals push ahead, until the crisis approaches and it is forced to cry, "help me, Cassius, or I sink."—*American Machinist.*

SCIENTIFIC PROGRESS.

The Origin of Comets.

In the exposition of his theory of the development of the solar system, Kant supposes the comets to be formed from the matter of the condensing solar nebula. By him they were regarded as planets, which, in some way, had been thrown out of their normally circular orbits. Laplace, on the other hand, in his exposition of the nebular hypothesis, took the ground that comets were formed from the matter which is scattered through the stellar spaces, and that in their origin they have no relation with the solar nebula. Have we, in the accumulation of facts since the days of Kant and Laplace, learned anything that may help us to decide between these theories? Such is the inquiry proposed by Prof. H. A. Newton, who in a recent number of the *American Journal of Science and Arts,* considers: First, what peculiarities each of them requires in the shape and distribution of the cometic orbits; and, second, compares with the theories the facts that have been observed with regard to the paths of 247 comets. The cometic paths are represented by the writer in two graphic curves, and when the results of actual observations are put into the same form, it is at first found that the curve thus obtained differs from both the theoretical ones. However, as the known comets all have their perihelion (that part of their orbit nearest the sun) within the orbit of Mars, and are exposed to planetary disturbances, the author calculates the influence of these disturbances, and arrives at the conclusion that the curve corresponding to the actual cometary paths is thus brought into good agreement with the theoretical curve deduced from Laplace's hypothesis, whereas it does not agree so well with that deduced from Kant's. It would seem, then, that the origin of comets must be placed in interstellar space.—*Scientific American.*

THE LAW OF THE TELEPHONE.—M. Hermann, has adduced certain experiments to show that du Bois Reymond's theory that the action of the telephone can be explained from the general law of induction in which the bending of the iron plate is taken into account, and the induction of the current path upon itself is neglected, does not explain the facts observed. Prof. H. F. Weber has written a paper in which he showed that Hermann's experiments agreed entirely with the theoretical laws of induction, and that Reymond was wrong in neglecting the induction of the current path upon itself, which last was really the principal agent in producing the agreement between theory and practice. Ten days later Helmholtz presented a paper to the Berlin Academy which covered the same ground as Prof. Weber's paper. The general results of these papers are as follows: (1.) "In the telephonic circuit the tone is in general altered." (2.) "The phase-displacement that occurs during the telphonic transit is not a constant quantity, its amount changes with the constitution of the path of the current, and depends on the number of vibrations." (3.) "In certain cases, however, the amplitude of the induced current becomes independent of the vibration number, and thus the tone of the exciting sound is unchanged."

A TOADSTOOL WITH THE ODOR OF CHLORINE.—A writer in the December number of the *Bulletin* of the Torrey Club records his discovery of a toadstool, which was exhaling a strong odor of chlorine when found, and which has been described as a new species by Mr. C. H. Peck, under the name of *Agaricus chlorinosmus.* The writer states that "there could be no doubt that the plant was exhaling chlorine, since there is no other substance known having the same, or even a remotely similar odor." From this he draws the inference that the "chlorine was taken up from the soil by the plant, in the form of a chloride, most probably the chloride of ammonium, or possibly of sodium." As a comment on this, the editor of the *Bulletin* calls attention to the fact that the Californian *eschscholtzia* is well known to have a colorless juice but with the odor of hydrochloric acid; yet this juice, on being tested, has been found to give not even a trace of chlorine, and "perhaps the same result will appear in the case of the new agaris." The odors of different fungi, like those of flowering plants, are almost as numerous and varied as the species themselves.—*Scientific American.*

THE BUBBLE IN SPIRIT-LEVELS.—In a recent part of the *Comptus Rendus* it is recorded that M. Plantamour made some observations upon the displacement of the bubble in spirit-levels, and found that there was a daily maximum during the afternoon, accompanied by gradual changes, which extended over a period of several successive days. In confirmation of his observations, M. d'Abbadie reported his own experience at Olinda, Brazil, in 1837; at Gondar, Ethiopia, in 1842; and subsequently, at Saqa. At each of these places the bubbles of the levels showed small variations in the direction of the plumb-line. Astronomers have doubtless suffered from these changes, without being aware of their cause, and have been obliged to mask them by taking the means of frequent observations.

POPLAR TREES AS LIGHTNING CONDUCTORS.—Observation has induced a very popular belief in Europe and throughout the northern Atlantic States, where poplar trees are cultivated, that lightning strikes these trees in preference to all others. Prof. Asa Gray, in a note to the *American Agriculturist,* says that the reason which lies at the bottom of this wide-spread opinion is coming to light. Green herbage, and green wood—sappy wood—are excellent conductors of electricity. A tree is shattered by lightning only when the discharge reaches the naked trunk or naked branches, which are poorer conductors. An old-fashioned Lombardy poplar, by its hight, by its complete covering of twigs and small branches, and their foliage down almost to the ground, and by its sappy wood, makes a capital lightning-rod, and a cheap one. Happily no one can patent it and bring it round in a wagon and insist upon trying it. To make it surer, the tree should stand in a moist ground or near water, for wet ground is a good conductor, and dry soil a poor one. It is recommended to plant a Lombardy poplar near the house, and another close to the barn. If the ground is dry, the nearer the well the better, except for the nuisance of the roots that will get into it.

THE PLANET MARS.—Prof. Lockyer is of the opinion that human life on the planet Mars may be very much like human life on the earth. The light cannot be so bright, but the organs of sight may be so much more susceptible as to make the vision quite as good. The heat is probably less, as the polar snows certainly extend further, but by no means less in proportion to the lessened power of the solar rays. The professor agrees with others that several remarkable seas—including inland seas, some of them connected and some not connected by straits with still larger seas—are now definable in the southern hemisphere, in which, as in the case also with the earth, water seems to be much more widely spread than in the northern hemisphere. There is, for example, a southern sea exceedingly like the Baltic in shape; and there is another and still more remarkable sea, now defined by the observation of many astronomers—one near the equator, a long straggling arm, twisting almost in the shape of an S laid on its back, from east to west, at least 1,000 miles in length, and 100 miles in breadth.

A NEW CHEMICAL—SILICIURETED HYDROGEN.—We have received from Dr. Theodor Schuchardt, of Goerlitz, a specimen of a new body which he calls silicium strontium. It is formed from the preparation of metallic strontium by electrolysis, but no particulars are given as to the substances present or the reaction by which it is formed. As received from Dr. Schuchardt, the compound is a gray powder with a slight odor resembling phosphuretod hydrogen. When mixed with diluted hydrochloric acid, a rapid evolution of the spontaneously inflammable siliciureted hydrogen takes place. No particulars as to price are mentioned, but, if obtainable in any quantity, this compound will probably be the readiest source of siliciureted hydrogen.—*Chemical News.*

SOLIDS IN SOLUTION.—There is something quite remarkable in regard to solids in solution. When in solution they assume the mechanical properties of liquids. The entire mass of the solution is in the liquid state, and, to all appearance, the molecules of the dissolved solid are as truly in the liquid condition as those of the solvent. Yet the molecules of the solid have not suffered any change of chemical composition. The natural inference then is, that they have experienced a change of mechanical condition. Something, perhaps, similar to the allotropic conditions of sulphur, phosperous, etc. The alternative supposition is that the physical molecules of the solid are more complex than the chemical molecules, and in the process of solution are broken up into others less complex, which, in their association, have the mechanical properties of a liquid.

ATMOSPHERIC VAPOR.—It is maintained by Dr. J. M. Anders that a large proportion of the vapor of the atmosphere may be accounted for through the process of transposition from plant life, where there is about from 25% to 30% of woodland in the country, and on this ground, considers that the practice of forest culture should be highly commended as a means of improving atmospheric conditions.

THE Telectroscope is the name proposed for a new apparatus designed by M. Senlecq, and which we are informed by *Nature,* is designed to reproduce, telegraphically, at a distance, the images obtained in the camera obscura. In this device the inventor has utilized the lately-observed sensitiveness of selenium to various shades of light.

GAS AND WATER PIPES AS A SOURCE OF ELECTRICITY.—Mr. C. O. Gregory, in a communication in the *English Mechanic,* states that he has successfully used the gas and water pipes in his dwelling as a source of electricity for a microphone. He connects one of his microphone wires with the gas pipe, the other with the water pipe, and finds the current ample, and, of course, constant.

Mining Share Market.

The past week has been peculiarly trying on the nerves of our stock people. Not that the unfavorable fluctuations have been so large, but the market has been so changeable, so fitful, that it has either led operators astray or left them in painful uncertainty as to what it would do next. There have, in fact, been several "breezes" during the week, but as nothing could be discovered to justify them, they fell almost as quickly as they rose. The weakness which characterized last week's proceedings was present at the opening of this, and the same slow, steady decline was plainly perceptible. A gentle upward push was given generally along the line on Monday. There was no regularity in the advance, but the general tendency was upward. The cause of it can only be conjectured. It is supposed to have been due to rumors of further negotiations between Mr. Sutro and the Comstock managers. The water stocks were strong at an advance in this "bullish" appearance, Union being the feature at the north end. On Tuesday the bruces were suddenly taken out and the propped market immediately fell, a general decline characterizing the day from opening to close. Toward the end of the week there was again a slight improvement, though, as heretofore, what caused the appreciation was kept in the background. At the finish, while there was depression in the prices of some securities, and all transactions were limited, there was an affecting rise in others, and the market closed with a quiet steadiness.

Additional Rights to Homestead Settlers.

Following is the full text of the act granting additional rights to homestead settlers on public lands within railroad limits, approved March 3d, just before the adjournment of the last Congress:

"*Be it enacted, etc.*, That from and after the passage of this act, the even sections within the limits of any grant of public lands to any railroad company, or to any State in aid of any railroad or military road, shall be open to settlers under the Homestead laws, to the extent of 160 acres to each settler; and any person who has, under existing laws, taken a homestead on any even section within the limits of any railroad or military road land grant, and who, by existing laws, shall have been restricted to 80 acres, may enter, under the Homestead laws, an additional 80 acres adjoining the land embraced in his original entry, if such additional land he subject to entry; or if such person so elect, he may surrender his entry to the United States for cancellation, and thereupon he entitled to enter lands under the Homestead laws the same as if the surrendered entry had not been made; and the person so making an additional entry of 80 acres, or a new entry after surrender and cancellation of his original entry, shall be permitted so to do without payment of fees and commissions; and the residence and cultivation of such person upon and of the land embraced in his original entry shall he considered residence and cultivation for the same length of time upon and of the land embraced in his additional or new entry, and shall be deducted from the five years residence and cultivation required by law: Provided, that in no case shall a patent issue upon an additional or new homestead entry under this act until the person has actually and in conformity with the Homestead laws, occupied, resided upon and cultivated the land embraced thereon at least one year.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments: Hillside, March 5th, $5,220; Tyho Con., March 1st, $4,119.89; Tyho Con., March 5th, $3,975.29; Standard, March 8th, $19,529.91; Northern Belle, March 5th, $6,196.99; Paradise Valley, March 9th, $2,843.25; Grand Prize, March 10th, $12,500; Hillside, March 11th, $4,740; Christy Con., March 11th, $5,463.

THE name of Rev. H. W. Reed has been stricken from the roll of the Baptist Minister's Meeting of San Francisco, for misrepresentations at the East regarding the Chinese question.

THE Central Pacific Railroad Company are doing a good business despite the dull times. The earnings for February came up to $1,093,000—a gain of $112,500.

THERE are said to be an average of 50 applicants for each of the subordinate vacant offices in the new Congress, and members are nearly distracted.

ARRANGEMENTS have been made for commencing work on the Canada Pacific railroad at an early date.

IT is stated that the position of director of the geological surveys will be given to Clarence King.

THE New York Bullion Club talk of building an edifice to cost $1,000,000.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MOORE.—*Ledger*, Mar. 8: The first clean-up at this mine was made this week. Including sulphurets it will average about $50 per ton.

VOLCANO DISTRICT ITEMS.—A clean-up of a crushing of 140 tons of ore from the Downs mine yielded $7,000. At the mine the indications are that there is more runs of satisfactory character in store. There is a ledge seven ft in width, all of high-grade ore; in fact it is probably the richest body of quartz in the county. The quartz is of a whitish character. The mine and mill give steady employment to 25 men. The survey has just been made of a road, 114 rods in length, at Cape Cruce gulch, between the mine and mill. A Santa Cruz company has located 40 acres of gravel mining ground, one and a half miles north of Volcano. The ground is supposed to be rich, but great difficulty has been experienced in getting rid of the water. The present company propose to put up an engine, sink a shaft and prospect in a thorough style. The Grass Valley gravel claim is in full blast, and the owners are sanguine of its success. The Volcano tunnel is in 1,300 ft, with over 900 ft still to be bored.

OTHER NOTES.—The Hercules is progressing finely; shaft down 100 ft. At the bottom a tunnel runs north along the vein 70 ft. It is now decided to put down the shaft 200 ft deeper. An improved method of hoisting rock at this mine consists of a self-dumping car. It needs no bucket-lander, and this effects a considerable saving. The Centennial mill is shortly to be started on ore from the Victoria. Fifteen tons are on the dump, estimated to yield $12 per ton. The Fort John mine is developing slowly. Work is let by contract, and only two men are employed. These parties claim the ground, and the prospect is fair for considerable litigation before the question of ownership is settled.

CALAVERAS.

BANNER MINE.—Cor. *Chronicle*, Mar. 8: The shaft has been sunk to 200 ft, bringing to light a well-developed vein, rich in precious metal. Its engine are 35 horse-power, and it employs 20 men.

SAN PEDRO.—This mine has attained a depth of 150 ft, with fine, regular walls from six to eight ft apart, encasing a true fissure vein.

HOEY & SLITER.—*Chronicle*, Mar. 8: Work was resumed in the Hoey & Sliter mine on the 3d inst., operations so far being confined to getting things in readiness for taking the water out. A San Francisco company has bonded the mine for 60 days, with the privilege of purchasing at the end of that time or abandoning it as they see fit.

MAMMOTH.—A clean-up has recently been made at the Mammoth hydraulic (J. C. Veith proprietor) that would be considered phenomenal if the claim was located anywhere else but here. It was large enough to permit the declaration of a dividend of about $4,000 per share. That, for a short run, is one of the best yields ever heard of. The Mammoth stands at the head of hydraulics in the middle and southern mines.

FRESNO.

FINE GOLD.—Cor. *Republican*, Mar. 5: Work in the Fresno Gold mining company's mines is in full blast. The works were started up on the 24th of February. Twenty men are now employed and a larger force will be put on as soon as the necessary arrangements can be made to work to advantage. Ore of a high grade is being taken out and the mine belonging to the company will be started up next week. Another five-stamp battery will soon be added.

LOS ANGELES.

SILVERADO.—Cor. Anaheim *Gazette*, Mar. 8: But little work has been done at any of the mines. The Blue Light company prosecuted work upon two tunnels, with six men employed, until about the 1st of February, when all work was suspended. This company is endeavoring to consummate arrangements with San Francisco parties for the erection of reduction works, two experts in the interest of those parties having visited and inspected the mine during the past month. Morgan & Mills have continued work during the entire winter on the Mountain Lode, and are sanguine of having developed a good paying ledge carrying both silver and gold. The mill enterprise of Capt. John L. Bray, of San Francisco, has not been consummated according to the original contract, which called for the completion of a 10-stamp mill on or before March 1st. The failure is reported to be caused by the illness of Capt. Bray and the death of his partner. Advices from Capt. Bray state that he now has arrangements completed for the fulfillment of the contract, with an extension of time. Sixty days further time is asked, which the interested parties will no doubt grant.

INYO.

GOOD PROPERTIES.—*Independent*, Mar. 1: Mining progress just now in and around Cerro Gordo is by no means slow. The Ygnacio is still yielding plenty of rich ore. The Diaz brothers are opening the San Lucas, in a four-ft ledge of splendid milling ore, sufficient to constantly supply a 10-stamp mill. The Palma mine, owned by Messrs. Hughes & Diaz, is producing fine ore and free gold. At the dump of the Guymas mine, being developed by Antoine Moreno, there is 60 tons of high-grade galena, and the property bids fair to equal the Union in value. The gold ledges of Beveridge district, since having been opened during the winter to the depth of 100 ft, show stronger and richer ore bodies at the bottom.

UNION CON.—Lately good miners have been in demand at Cerro Gordo. Since the visit of Messrs. Belshaw & Beaudry, some two or three weeks ago, work has been pushed ahead in all matters with increased vigor. New drifts have been started, and all of them look well. The water-works, after lying idle all winter, during which snow was used instead, were started up the 23d ult. The lower furnace is to be fired up again soon for a long run.

MONO.

RED CLOUD CON.—Bodie *Standard*, Mar. 10: On the 400 level the Red Cloud ledge has been cut at a point 155 ft from the shaft. The ledge is about three ft wide, and contains the same blue rock which characterized it in the levels above. Drifts have been started north and south on the ledge. The west crosscut, same level, is now in 94 ft. The blue rock in this crosscut has given way to the reddish-brown porphyry, characteristic of the 250 level, and in which the best mines of the district have been found. The indications now are that the country is pitching to the east, while it seemed to be pitching west on the 250 level. On the 250 level the winze on the Packard and Morton ledge was stopped at a depth of 25 ft, in consequence of the accumulation of water, of which there is considerable in this ledge. All down the winze the same fine prospects in coarse gold could be obtained which were found when the ledge was first cut. The west crosscut, from the north drift of the same level, has cut through two ft of clay, and appears to be in the casing of the ledge.

BLACKHAWK.—The Warren vein, which was struck last week on the 220 level, new shaft, has been developed to a distance of 12 ft south from the crosscut, showing a fine four-ft ledge of valuable gold-bearing quartz. A north drift has also been started, which shows the vein in that direction to as good advantage as in the south. The crosscut is being advanced west for the second ledge, in exceedingly hard porphyry. Work has been retarded by visitors. The second ledge will be struck in a few days. The shaft is now down 805 ft. At 320 ft another level will be started, and a crosscut run for the ledge again.

STANDARD.—No change in the east crosscut from the main shaft; total length, 328 ft; progress for the week, 28 ft. The south drift from the crosscut has been advanced during the week 22 ft. The ledge is four ft wide, and looks well. The north drift from the east crosscut, 500 level, has been run 14 ft; total length, 90 ft. The ledge here is two ft wide of very good ore. North drift on West Standard is in 100 ft from west crosscut. The ledge is 18 inches wide of very rich ore. Connection has been made between the West Standard south drift and the drift coming from the south line. The ledges have come together. The north drift on the Cook ledge is in 150 ft from the southern boundary. The ledge is 18 inches wide, of very fine ore.

CON. PACIFIC.—The winze being sunk on ledge No. 2, 65 ft from the mouth of the tunnel, is down 57 ft. The ledge has pitched eastward so as to constitute the hanging wall of the winze, and is over 20 inches in width of an improved grade of ore. Progress will be more speedy hereafter, as three shifts of men will be employed. Work on the new central shaft, 550 ft south of the winze, was resumed on Saturday with increased force, and will be continued as a double-compartment and timbered with square sets. It is now 172 ft in depth, with indications of a favorable formation for crosscutting.

MARYLAND CON.—Work upon this mine is being pushed as rapidly as possible by the company. Their shaft is now in red porphyry and a ledge of considerable size of decomposed quartz. A crosscut will shortly be started for the Bonanza ledge, as there is no better showing in the camp.

AN IMPORTANT WORK.—The north drift from the Mono shaft, 400 level, has reached the Bodie line, 125 ft north of the Mono hoisting works. A crosscut will at once be run east and west the entire width of the two mines, 600 ft, and a station for a turn-table, etc., is now being cut out at the boundary line. This work is one of great importance. The 400 level of the Mono is equivalent to the 500 level of the Bodie new shaft. The proposed crosscut will be very likely to demonstrate what there is in the south end of the Bodie mine, as well as the value of the Mono.

NEVADA.

THE HUDSON MINE.—*Herald*, Mar. 9: The shaft is down 155 ft, and the ledge keeps improving in thickness, quality of rock, and is becoming better defined. At the bottom of the shaft the ledge is five feet thick. The stoping thus far has been done on the south side toward Deer creek. The mine was bonded some time ago, and the parties bonding will, without doubt, effect a sale to an Eastern company. A new road has been graded from the Pleasant valley road along the brow of the Beckman hill down to the mine.

BLOOMFIELD MINE.—The company are now washing through shaft No. 0, which is the uprise at the end of the main tunnel. They will still use shaft No. 8, which has been the inlet into the branch tunnel heretofore in use, in case of stoppage of operations in shaft No. 9, so that no time need be lost.

PROVIDENCE MINE.—The uprise for the new shaft, at the Providence mine, has been completed. The shaft was started from the 000 level, and from the starting point to the place where it comes to the surface on the side of the hill is nearly 800 ft. Some very rich rock was cut through in making the uprise. The new shaft gives a splendid chance for air. The air now is just as pure as at the surface.

SNEATH & CLAY MINE.—This mine has been recently purchased by Messrs. Shoecraft & Sprague. It is proposed to incorporate it and sell the stock here. The stock of the company is divided into 100,000 shares at a par value of $10 per share. The property consists of 1,100 ft of gold-bearing quartz. There is a 12-stamp mill on the mine, with hoisting works, and these are supplied with three engines and two boilers. Besides there are sheds and other necessary buildings. It will cost about $1,500 to start everything in working shape. The incline is down 470 ft, with four levels which have been run, and from which over $400,000 were taken out; the company will incorporate as soon as 40,000 shares of the capital stock has been subscribed. The mine is at present in the hands of mining engineer, Fred. A. Sacket, Esq., who is receiving subscriptions for the stock.

THE DEADWOOD MINE.—*Transcript*, Mar. 7: The average amount of ore now being extracted is 15 tons to every 24 hours. A crushing of 185 tons has just been made, and there is besides 200 tons more on the dump. Workmen are engaged in attaching pipes so that in a few days the mill and hoisting works will be run by hurdy-gurdy power at an expense not exceeding $4 or $5 per day.

THE SMITH MINE.—The north drift is now in over 50 ft. The last 12 ft of it has been in solid boulders, but there is a good prospect for shortly being in soft granite again. The drift extends along a small ledge that increases in size and quality as it is developed. It is expected that 150 ft more will reach the rich chute that was formerly worked down on 80 ft and paid over $100 per ton. The chute is supposed to be at least 200 ft long.

PLACER.

THE KEEHNER & HOLER QUARTZ MINE.—*Herald*, Mar. 8: Messrs. Keehner & Holer are now sinking a shaft on the old New York ledge, on the old Poland ranch. The shaft is now down 38 ft. They have raised 26 tons, which milled at the rate of $13 per ton. This enterprise shows that there is an abundance of quartz in and around Duncan hill which may be made remunerative by the application of individual industry.

THE BOOTH QUARTZ MINE.—This mine is now leased to Messrs. Robinson, Ferguson and Gould Bros. The shaft is down 175 ft. The hoisting works, which are operated by a whim and horse-power, are in fine working order. The rock pays from $8 to $10 per ton. The ledge is from two to five ft in width. The indications now are that the company is raising excellent milling rock, to be crushed in Messrs. Simons & Palster's quartz mill on North Ravine. The Booth mine failed to be remunerative in the hands of a stock company some years since, but under the control of practical miners its bids fair to become valuable property.

IOWA HILL ITEMS.—J. B. Hobson's claim, at Independence hill, had run seven days when it was compelled to shut down for want of water. The Orion mine is owned by capitalists of Springfield, Mass., and San Francisco. The superintendent is W. W. Anderson, of Gold Run, an experienced and thorough miner. Night and day shifts of men are working on the rimrock and into the Sugar Loaf. They are at present using about 625 inches of water, and expect to have as much more for use. At the Morning Star nothing can be done until they have a supply of water in the big ditch. Watts Bros. have a small claim on Strawberry Flat in which washing is going on, the water supply coming from Indian canyon. The men have some heavy rock to work and found it necessary, on this account, to put up a powerful derrick last fall. The mast is 60 ft high and the boom 50 ft in length. Entwistle's claim is running with 250 inches of water. Joseph Byrne and David Beardsley are about to work a 10-stamp mill on the Columbus mine on Roach hill. John Mills has a small hydraulic mine which will pay well this season if he gets the necessary water. Anton Phillips, a Portuguese, has a hydraulic claim here that has always paid well when the water season permitted of its being worked. The owner generally has two or three men besides himself to operate ft. The mine has not been worked this season.

SHASTA.

WHISKYTOWN.—Cor. Reading *Independent*, Mar. 6: Knox, Woodward & Co. have run a tunnel on their lead about 100 ft. Although they have run through some very inferior rock, they have now reached a place where it prospects very rich indeed. They have quite an amount of quartz on hand and are running the arastra as fast as the water will permit. A clean-up of some of the quartz taken out last summer yielded about $60 per ton. Mr. Banghart's mine, same diggings, on Mad Mule, is yielding very rich. We have just seen weighed over 40 ounces of pure gold, which he lately took out in one day. He has run a tunnel into the hill several hundred ft. He expects to reach a very rich point soon, at which he sank a shaft last summer, but owing to the water, could not sink it further. The Morning Light, a new mine recently discovered at the head of Murderer's gulch, about one mile west of Whiskytown, is prospecting well. A tunnel is being run and it is expected that the ledge will be reached within a few days. At the Peckham mine, now owned by Stroud & Co., the work is being pushed quite rapidly. The mill has been received on the ground and will be in operation within a few weeks. Work on the extension is being rapidly pushed forward. Their arastra runs night and day, but on account of scarcity of water, can do but little more than half work. Williams & Ketchum are working their claim on Saw Mill flat. They have an abundance of water and are receiving good returns.

TUOLUMNE.

A NEW INTEREST.—*Union-Democrat*, Mar. 8: The Seeber claim, a short distance below town, begins to assume an appearance of business. The shaft has already been sunk to a depth of 40 ft. The vein is about 18 inches wide. The rock taken out looks well, and the parties at work represent that it prospects encouragingly. The intention is to sink to a depth of about 50 ft, and then to start a drift. The bottom of the shaft is now several ft below the bed of Woods creek, and water begins to retard the work. The present outlook of the mine is promising, and it is to be hoped that it will prove a success.

NEVADA.

WASHOE DISTRICT.

CALIFORNIA.—Gold Hill *News*, Mar. 12: The drift, 1650 level, connecting the C & C shaft and the Con. Virginia shaft, is receiving needed repairs. The joint Con. Virginia winze from the 1950 level is down 67 ft, and still in hard blasting porphyry. The joint drift on the 2150 level continues to make rapid progress in hard blasting porphyry. The C & C shaft is cutting dry, hard rock, and nearing the 2300 level. The daily yield of this mine is about 240 tons.

MEXICAN.—A joint Ophir upraise has been started from the 2100 level of the Ophir to meet the drift running north on the 2000 level for ventilation. The joint Union Con. incline winze is now 278 ft on the slope below the 1600 level, and in hard blasting porphyry. The north drift, 2000 level, continues in soft porphyry, through which it is making seven ft per day.

OPHIR.—Repairs to the main shaft, above the 1465 level, have been continued. Work in the incline has been resumed. From the main north drift, 2100 level, a joint Mexican upraise has been started for the 2000 level for ventilation.

SAVAGE.—The pumps are holding the water at the 2040 tank. Repairs to the vertical shaft and incline continues.

EXCHEQUER.—North drift, 2400 level, is in soft ground, requiring to be timbered. The vein widens as this drift is pushed on north.

CON. VIRGINIA.—Repairs to the shaft below the 1400 level have been rendered necessary by its gradual sliding to the east so as to interfere with the running of the cages. Repairs to the 1050 connecting drift are being made. The joint California winze is making two ft per day through hard porphyry. Three ft per day are being made in the joint drift 2150 level to connect with the joint winze, the material encountered being porphyry.

SIERRA NEVADA.—The sump at the bottom of the east shaft has been completed and a drift started on the 2200 level in that coming north from the incline. It is now 60 ft below the 2300 level. The north drift, 2200 level, is still in soft ground, the face 390 ft from the north crosscut. Good progress is being made in the upraise from the 1700 level to connect with the North Con. Virginia shaft.

GOULD & CURRY.—Repairs last week stopped developments, but work is now making usual progress. The winze on the Savage line is being sunk from the 1900 level to the 2000 level, and crosscuts east are being run joint with the Best & Belcher on both the 1700 and 1900 levels. The Osbiston shaft is still encountering a heavy flow of water, the pumps raising 30 miners' inches.

NORTH BONANZA AND FLOWERY.—The water tank at the 300 level of the joint shaft is ready to talk and the rock chute is completed. An engine of sufficient capacity to sink 2,000 ft was bought yesterday, and will soon be placed in position. The north drift is following the ledge at the rate of six ft per day. There is no water there to hinder operations.

BELCHER.—The main incline is now 125 ft below the 2560 level. The south drift on the 2560 level is averaging seven ft per day.

UTAH.—Repairs to the incline during the past week have somewhat delayed operations at other points. A water tank has been put in near the bottom of the incline, so as to be in readiness when the standing pumps are in place.

OVERMAN.—The winze from the 1600 level is still in porphyry containing streaks of quartz, which are increasing in size with depth. The north drift, 1000 level, is in soft vein matter from which some water seeps in. The O & C shaft is down 470 ft in good working ground.

YELLOW JACKET.—Put in the new air-compressor. The engine of the compressor is now on its bed. The work of putting in the air pipes is progressing well.

HALE & NORCROSS.—The winze from the east drift, 2000 level, is nearing the 2100 level. The pumps are all holding the water below the 2000 level.

CROWN POINT.—The north drift, 2500 level, is still skirting the ore vein, laying it bare ready for crosscutting.

BULLION.—An airway is being cut in the crosscut, 1840 level, for better ventilation. The formation encountered is still porphyry and quartz. The foundation stones for the new air compressor are being laid, and the shaft is undergoing repairs at the 500 station.

BEST & BELCHER.—The general overhauling at the Gould & Curry last week interfered with work in the mine somewhat, but operations are now going on as usual. A joint drift is being run with Con. Virginia west on the 1700 level and joint crosscuts east with the Gould & Curry on both the 1700 and 1900 levels.

JULIA CON.—Pumping to the surface and into the Sutro Tunnel. The sprung and twisted reel shaft has been replaced by a new one. The bailing tanks have been taken out of the shaft. There has been a good down current of air again given to the north compartment of the shaft. The 2000 level has not yet been freed from water.

MT. HOOD & VANCOUVER.—Last evening the 1400 level of the Mint shaft was drained and the water was taken from the sump 25 ft below that level.

WARD.—Work in the east crosscut, 800 level, will be resumed the last of this week. The men are digging the trench for the water pipe from the tank to the works. The new engine will start as soon as the new skeet is ready for use.

NORTH CON. VIRGINIA.—The shaft is still encountering the hardest kind of rock, but making three ft per day. It will connect with the upraise from the 1700 level of the Sierra Nevada in about 10 days.

UNION CON.—The work of enlarging and retimbering the north drift, 1450 level, connecting with the Sierra Nevada, continues. The joint Mexican winze from the 1000 level is down 278 st on the slope, in hard blasting porphyry.

CHOLLAR-COMBINATION SHAFT.—The work of putting in the 6-inch pipe for the air compressor has been completed, and the compressor itself is being put in place as fast as possible.

JUSTICE.—At the old Waller Defeat ground, three shifts of seven men each are employed extracting ore which is being worked at the Pappoose mill. The capacity of this mill is 20 tons per day, and it is kept running.

CON. IMPERIAL.—South drift, 2200 level, to connect with the old workings of the Yellow Jacket, is in 50 ft, and in fine looking quartz.

LADY BRYAN.—Sinking below the 600 level as usual. The drifts north and south on this level are still being driven ahead and making good progress. The one to the south is in very fine looking quartz, but of low grade. The one north is outside the quartz formation, but is still in the vein.

LEVIATHAN.—The face of the north lateral drift on the

[Continued on Page 172.]

Mining Share Market.

The past week has been peculiarly trying on the nerves of our stock people. Not that the unfavorable fluctuations have been so large, but the market has been so chaugeable, so fitful, that it has eitber led operators astray or left them in painful uncertainty as to what it would do next. There have, in fact, been sovoral "breezes" during the week, but as nothing conld be discovered to justify them, they fell almost as quickly as they rose. Tbe weakness which characterized last week's proceedings was present at the opening of this, and the same slow, steady decline was plainly perceptible. A gentle upward push was given generally along the line on Monday. There was no regularity in the advauce, but the general tendeucy was upward. The cause of it can only be coujectured. It is supposed to have been due to rumors of further negotiatious between Mr. Sutro and the Comstock managers. The water stocks were strong at an advance in this "bullish" appearance, Union being the feature at the north end. On Tuesday the braces were suddenly taken out and the propped market immediately fell, a general decline characterizing the day from opening to close. Toward the end of the week there was again a slight improvement, though, as heretofore, what caused the appreciation was kept in the background. At the finish, while there was depressiou in the prices of some securities, and all transactions were limited, there was an affecting rise in others, and the market closed with a quiet steadiness.

Additional Rights to Homestead Settlers.

Following is the full text of the act granting additional rights to bomestead settlers on public lands within railroad limits, approved March 3d, just before the adjournment of the last Congress:

"*Be it enacted, etc.*, That from and after the passage of this act, the even sections within the limits of any graut of public lands to any railroad company, or to any State in aid of any railroad or military road, shall bo open to settlers under the Homestead laws, to the extent of 160 acres to each settler; and any person who bas, under existing laws, taken a homestead on any even section within the limits of any railroad or military road land grant, and who, by existing laws, shall have been restricted to 80 acres, may enter, under the Homestead laws, an additional 80 acres adjoining the land embraced in his original entry, if sucb additional land be subject to entry; or if such person so elect, be may surrender his entry to the United States for cancellatiou, and tbereupon be entitled to enter lands under the Homestead laws the same as if the surrendered entry bad not been made; and the person so making an additional entry of 80 acres, or a new entry after surrender and cancellation of bis original entry, shall be permitted so to do without payment of fees and commissions; and the residence and cultivation of such person upon and of the land embraced in his original entry shall he considered residence and cultivation for ,the same length of time upon and of tbe land embraced in his additional or new entry, and shall be deducted from the five years residence and cultivation required by law: Provided, tbat in no case shall a patent issue upon an additional or new homestead entry under this act until tbe person has actually and in conformity with the Homestead laws, occupied, (resided upon and cultivated tbe land embraced thereon at least one year.

Bullion Shipments.

Since our last issue, we have noticed tbe following bullion sbipments: Hillside, March 5tb, $5,220; Tybo Con., March 1st, $4,119.89; Tybo Con., March 5tb, $3,975.29; Standard, March 8th, $19,529.91; Nortbern Belle, March 5th, $6,196.99; Paradise Valley, March 9tb, $2,843.25; Grand Prize, March 10tb, $12,500; Hillside, March 11tb, $4,740; Christy Con., March 11tb, $5,463.

THE name of Rev. H. W. Reed has been stricken from tbe roll of tbe Baptist Minister's Meeting of San Francisco, for misrepresentations at the East regarding the Chinese question.

THE Central Pacific Railroad Company are doing a good business despite the dull times. The earuings for February came up to $1,093,000—a gain of $112,500.

THERE are said to be an average of 50 applicants for each of the subordinate vacant offices in the new Congress, and members are nearly distracted.

ARRANGEMENTS bave been made for commencing work on tbe Canada Pacific railroad at an early date.

IT is stated that the position of director of the geological surveys will be given to Clarence King.

T[illegible] New York Bullion Clnb talk of building an [illegible] to cost $1,000,000.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MOORE. *Ledger*, Mar. 8: The first clean-up at this mine was made this week. Including sulphurets it will average about $10 per ton.

VOLCANO DISTRICT ITEMS.—A clean-up of a crushing of 140 tons of ore from the Downs mine yielded $7,000. At the mine the indications are that there is more runs of satisfactory character in store. There is a ledge seven ft in width, and of high-grade ore; in fact it is probably the richest body of quartz in the county. The quartz is of a whitish character. The mine and mill give steady employment to 65 men. The survey has just been made of a road, 14 miles in length, at Cape Cruz gulch, between the mine and mill. A Santa Cruz company has located 40 acres of gravel mining ground, one and a half miles north of Volcano. The ground is supposed to be rich, but great difficulty has been experienced in getting rid of the water. The present company propose to put up an engine, sink a shaft and prospect in a thorough style. The Grass Valley gravel claims are in full blast, and the owners are sanguine of its success. The Volcano tunnel is in 1,300 ft, with over 900 ft still to be bored.

OTHER NEWS.—The Hercules is progressing finely; shaft down 100 ft. At the bottom a tunnel runs north along the vein 70 ft. It is now decided to put down the shaft 200 ft deeper. An improved method of hoisting rock at this mine consists of a self-dumping car. It needs no bucket-hand, and this effects a considerable saving. The Centennial is still working. One night last week the shaft belonging to the rope-drum was twisted off. The Centennial mill shortly to be started on ore from the Victoria. Fifty tons are on the dump, estimated to yield $12 per ton. The Fort John mine is developing slowly. Work is let by contract, and only two men are employed. These parties claim the ground, and the prospect is fair for considerable litigation before the question of ownership is settled.

CALAVERAS.

BANNER MINE.—Cor. *Chronicle*, Mar. 8: The shaft bas been sunk to 100 ft, bringing to light a well-developed vein, rich in precious metal. Its engine are 35 horse-power, and employs 20 men.

SAN PEDRO.—This mine has attained a depth of 150 ft, with fine, regular walls from six to eight ft apart, encasing a true flume vein.

HOEY & STERR.—*Chronicle*, Mar. 8: Work was resumed in the Hoisy & Sliter mine on the 3d inst., operations so far being confined to getting things in readiness for taking water out. A San Francisco company has bonded the mine for 60 days, with the privilege of purchasing at the end of that time or abandoning it as they see fit.

MAMMOTH. A clean-up has recently been made at the Mammoth hydraulic (J. C. Veith proprictor) that would be considered phenomenal if the claim was located anywhere else but here. It was large enough to permit the declaration of a dividend of about $4,000 per share. That, for a short run, is one of the best yields ever heard of. The Mammoth stands at the head of hydraulics in the middle and southern mines.

FRESNO.

FINE GOLD.—Cor. *Republican*, Mar. 5: Work in the Fresno Gold Mining company's mines is in full blast. The works were started up on the 24th of February. Twenty men are now employed and a larger force will be put on as soon as the necessary arrangements can be made to work to advantage. Ore of a high grade is being taksn out and the mine belonging to the company will be started up next week. Another five-stamp battery will soon be added.

LOS ANGELES.

SILVERADO. Cor. Anaheim *Gazette*, Mar. 8: But little work has been done at any of the mines. The Blue Light company prosecuted work upon two tunnels, with six men employed, until about the 1st of February, when all work was suspended. This company is endeavoring to consummate arrangements with San Francisco parties for the erection of reduction works, two experts in the interest of those parties having visited and inspected the mine during the past month. Morgan & Mills have continued work during the entire winter on the Mountain Lode, and are sanguine having developed a good paying ledge carrying both silver and gold. The mill enterprise of Capt. John L. Bray of San Francisco, has not been consummated according to the original contract, which called for the completion of a 10-stamp mill on or before March 1st. The failure is reported to be caused by the illness of Capt. Bray and the death of his partner. Advices from Capt. Bray state that he now has arrangements completed for the fulfillment of the contract, with an extension of time. Sixty days further time is asked, which the interested parties will no doubt grant.

INYO.

GOOD PROPERTIES.—*Independent*, Mar. 1: Mining progress just now and around Cerro Gordo is by no means slow. The Yucio is still yielding plenty of rich ore. The Diaz brothers are opening the San Lucas, in a four-ft ledge of splendid milling ore, sufficient to constantly supply a 10-stamp mill. The Palma mine, owned by Messrs. Hughes & Dix, is producing fine ore and free gold. At the dump of the Guymas mine, being developed by Antoine Moreno, there is 60 tons of high-grade galena, and the property bids fair to equal the Union in value. The gold ledge of Beveridge district, since having been opened during the winter to the depth of 100 ft, show stronger and richer ore bodies at the bottom.

UNION CON.—Lately good miners have been in demand at Cerro Gordo. Since the visit of Messrs. Belshaw & Beaudry, some two or three weeks ago, work has been pushed ahead all matters with increased vigor. New drifts have be started, and all of them look well. The water-works, after lying idle all winter, during which snow was used, were started up on the 23d inst. The lower furnace is to be fired up again soon for a long run.

MONO.

RED CLOUD CON.—Bodie *Standard*, Mar. 10: On the 400 level the Red Cloud ledge bas been cut at a point 155 ft from the shaft. The ledge is about three ft wids, and contains the same ore rock which characterized it in the levels above. Drifts have been started north and south on the ledge. The west crosscut, same level, is now in 94 ft. The blue rock in this crosscut has given way to the reddish-brown porphyry, characteristic of the 250 level, and in which the best mines of the district have been found. The indications now are that the country is pitching to the east, while it sssmed to be pitching west on the 250 level. On the 250 level the winze on the Packard and Morton ledge was stopped at a depth of 25 ft, in consequsnce of the accumulation of water, of which there is considerable in this ledge. All down this winze the same fine prospects in coarse gold could be obtained which were found when the ledge was first cut. The west crosscut, from the north drift of the same level, has cut through two ft of clay, and appears to be in the casing of the ledge.

BLACKHAWK. The Warren vein, which was struck last week on the 200 level, new shaft, has been developed to a distance of 12 ft south from the crosscut, showing a fine four-ft ledge of valuable gold-bsaring quartz. A north drift has also been started, which shows the vein in that direction to a good advantage as in the south. The crosscut is both advanced west for the second ledge, in exceedingly hard porphyry. Work has been retarded by visitors. The second ledge will be struck in a few days. The shaft is now down 305 ft. At 320 ft another level will be started, and a crosscut run for the ledge again.

STANDARD. [illegible] change in tbe east crosscut from this main shaft; total length, 328 ft; progress for the week, 28 ft. The south drift from the crosscut has been advanced during the week 22 ft. The ledge is four ft wide, and looks well. The north drift from the east crosscut, 300 level, has been run 14 ft; total length, 96 ft. The ledge here is two ft wide of very good ore. North drift on West Standard is in 100 ft from west crosscut. The ledge is 18 inches wide of very rich ore. Connection has been made between the West Standard south drift and the drift coming from the south line. The ledges have come together. The north drift on the Cook ledge is in 150 ft from the southern boundary. The ledge is 18 inches wide, of very fine ore.

CON. PACIFIC.—The winze being sunk on ledge No. 2, 65 ft from the month of the tunnel, is down 57 ft. The ledge has pitched eastward so as to constitute tbe hanging wall of this winze, and is over 20 inches in width of an improved grade of ore. Progress will be more speedy hereafter, as three shifts of men will be employed. Work on the new central shaft, 550 ft south of the winze, was resumed on Saturday with increased force, and will be continued as a double-compartment and timbered with square sets. It is now 172 ft in depth, with indications of a favorable formation for crosscutting.

MARYLAND CON.—Work upon this mine is being pushed as rapidly as possible by the company. Their shaft is now in red porphyry and a ledge of considerable size of decomposed quartz. A crosscut will shortly be started for the Bonanza ledge, as there is no better showing in the camp.

AN IMPORTANT WORK.—The north drift from this Mono shaft, 400 level, has reached the Bodie line, 125 ft north of the Mono hoisting works. A crosscut will at once be run east and west tbis entire width of the two mines, 600 ft, and a station for a turn-table, etc., is now being cut out at the boundary line. This work is one of great importance. The 400 level of the Mono is equivalent to the 500 level of the Bodie new shaft. The proposed crosscut will bo very likely to demonstrate what there is in the south end of the Bodlo mine, as well as the value of this Mono.

NEVADA.

THE HUDSON MINE.—*Herald*, Mar. 0: The shaft is down 155 ft, and the ledge keeps improving in thickness, quality of rock, and is becoming better defined. At the bottom of the shaft the ledge is five feet thick. Tbe stoping thus far has been done on the south side toward Deer creek. The mins was bonded some tims ago, and the parties bonding will, without doubt, effect a sale to an Eastern company. A nsw road has been graded from the Pleasant valley road along the brow of tho Beckman bill down to the mine.

BLOOMFIELD MINE.—Tbe company are now washing through shaft No. 9, which is the uprise at the end of this main tunnel. They will still use sbaft No. 8, wbich has been the inlet into the branch tunuel beretofore in use, in case of stoppage of operations in shaft No. 9, so that no time need be lost.

PROVIDENCE MINE.—The upriss for the new sbaft, at the Providence mine, has been completed. The shaft was started from ths 600 level, and from the starting point to the place where it comes to the surface on the side of the hill is nearly 800 ft. Soms very rich rock was cut through in making the upriss. The new shaft gives a splendid chance for air. The air now is just as pure as at the surface.

SNEATH & CLAY MINE.—This mine has been rscently purchased by Messrs. Shoecraft & Sprague. It is proposed to incorporate it and sell the stock here. The stock of the company is divided into 100,000 shares at a par value of $10 psr share. The property consists of 1,100 ft of gold-bearing quartz. There is a 12-stamp mill on the mine, with hoisting works, and these are supplied with three engines and two boilers. Besides there are sheds and other necessary buildings. It will cost about $1,500 to start everything in working shape. The incline is down 470 ft, with four levels which bavs been run, and from which over $400,000 were taken out; the company will incorporate as soon as 40,000 shares of the capital stock has been subscribed. The mine is at present in ths hands of mining engineer, Fred. A. Sacket, Esq., who is receiving subscriptions for the stock.

THE DEADWOOD MINE.—*Transcript*, Mar. 7: The average amount of ore now being extracted is 15 tons to every 24 hours. A crushing of 185 tons has just been made, and there is besides 200 tons more on the dump. Workmen are engaged in attaching pipes so that in a few days the mill and hoisting works will be run by hurdy-gurdy power at an expense not exceeding $4 or $5 per day.

THE SMITH MINE.—The north drift is now in over 50 ft. The last 12 ft of it has been in solid boulders, but there is a good prospect for shortly being in soft granite again. The drift extends along a small ledge tbat increases in size and quality as it is developed. It is expected tbat 150 ft more will reach the rich chute that was formerly worked down on 80 ft and paid over $100 per ton. The chute is supposed to be at least 200 ft long.

PLACER.

THE KEEHNER & HOLER QUARTZ MINE.—*Herald*, Mar. 8: Messrs. Keehner & Holer are now sinking a shaft on tbs old New York ledge, on the old Poland ranch. The shaft is now down 38 ft. They bave raised 26 tons, which milled at the rate of $13 per ton. This enterprise shows that there is an abundance of quartz in and around Duncan hill which may be made remunerative by the application of individual industry.

THE BOOTH QUARTZ MINE.—This mine is now leased to Messrs. Robinson, Ferguson and Gould Bros. Tbe shaft is down 175 ft. The hoisting works, which are operated by a whim and horse-power, are in fine working order. The rock pays from $8 to $10 per ton. The ledge is from two to five ft in width. The indications now are that the company is raisiug sxcellent milling rock, to be erushed in Messrs. Simons & Pelster's quartz mill on North Ravine. The Booth mine failed to be remunerative in the hands of a stock company some years since, but undsr the control of practical miners its bids fair to become valuable property.

IOWA HILL ITEMS.—J. B. Hobson's claim, at Independence hill, had run seven days when it was compelled to shut down for want of water. The Orion mins is owned by capitalists of Springfield, Mass., and San Francisco. The superintendent is W. W. Anderson, of Gold Run, an experienced and thorough miner. Night and day shifts of men are working on the rimrock and into tbe Sugar Loaf. They are at present using about 625 inches of water, and expect to have as much more for use. At the Morning Star nothing can be done until they have a supply of water in the big ditch. Watts Bros. bavs a small claim on Strawberry Flat in which washing is going on, the water supply coming from Indian canyon. Ths men have some heavy rock to work and found it necessary, on this account, to put up a powerful derrick last fall. The mast is 60 ft high and the boom 50 ft in length. Entwistle's claim is running with 250 inches of water. Joseph Byrne and David Beardsley are about to work a 10-stamp mill on the Columbus mine on Roach hill. John Mills has a small hydraulic mine which will pay well this season if he gets the necessary water. Anton Phillips, a Portuguese, has a hydraulic claim here that has always paid well when ths watsr season permitted of its being worked. The owner generally has two or three men besides himself to operate it. The mine has not been worked this season.

SHASTA.

WHISKYTOWN.—Cor. Reading *Independent*, Mar. 6: Knox, Woodward & Co. have run a tunnel on their lead about 100 ft. Although they have run through some very inferior rock, they have now reached a place where it prospects very rich indeed. They have quite an amount of quartz on hand and are running the arastra as fast as the water will permit. A clean-up of some of the quartz taken out last summer yielded about $80 per ton. Mr. Banghart's mins, same diggings, on Mad Mule, is yielding very rich. We have just seen weighed over 40 ounces of pure gold, which he lately took out in one day. He has run a tunnel into the hill several hundred ft. He expects to reach a very rich point soon, at which he sank a shaft last summer, but owing to the water, could not sink it further. Ths Morning Light, a new mine recently discovered at the head of Murderer's gulch, about one mile west of Whiskytown, is prospecting well. A tunnel is being run and it is expected that the ledge will be reached within a few days. At the Peckham mine, now owned by Stroud & Co., the work is being pushed quite rapidly. The mill has been received on the ground and will be in operation within a few weeks. Work on the extension is being rapidly pushed forward. Their arastra runs night and day, but on account of scarcity of water, can do but little more than half work. Williams & Ketchum are working their claim on Saw Mill flat. They have an abundance of water and are receiving good returns.

TUOLUMNE.

A NEW INTEREST.—*Union-Democrat*, Mar. 8: Th Scsbcr claim, a short distance below town, begins to assume an appearance of business. The shaft has already been sunk to a depth of 40 ft. Ths vein is about 18 inches wide. The rock taken out looks well, and the parties at work represent that it prospects encouragingly. The intention is to sink to a depth of about 50 ft, and then to start a drift. The bottom of the shaft is now several ft below the bed of Woods creek, and water begins to retard the work. The present outlook of the mine is promising, and it is to bs hoped that it will prove a success.

NEVADA.

WASHOE DISTRICT.

CALIFORNIA.—Gold Hill *News*, Mar. 12: The drift, 1650 level, connecting the C & C shaft and the Con. Virginia shaft, is receiving needed repairs. The joint Con. Virginia winze from the 1950 level is down 07 ft, and still in hard blasting porphyry. The joint drift on the 2150 level continues to make rapid progress in hard blasting porphyry. The C & C shaft is cutting dry, hard rock, and nearing the 2300 level. Tbe daily yield of the mine is about 240 tons.

MEXICAN.—A joint Ophir upraise has been started from tbe 2100 level of the Ophir to meet the drift running north on the 2000 level for ventilation. The joint Union Con. ineline winzs is now 278 ft ou the slope bslow the 1600 level, and in hard blasting porphyry. The nortb drift, 2000 level, continues in soft porphyry, through which it is making ssven ft per day.

OPHIR.—Repairs to the main shaft, above the 1465 lsvel, bavo been continued. Work in tbe ineline has been resumed. From the main north drift, 2100 level, a joint Mexican upraise has been started fer the 2000 level for ventilation.

SAVAGE.—The pumps are holding the water at the 2040 tank. Repairs to the vertical sbaft and incline continues.

EXCHEQUER.—North drift, 2400 level, is in soft ground, requiring to be timbered. The vsin widens as tbis drift is pusbed on north.

CON. VIRGINIA.—Repairs to the shaft below the 1400 level have been rendered necessary by its gradual sliding to the east so as to interfere with the running of tbe cages. Repairs to the 1650 connecting drift are being made. The joint California winze is making two ft per day through hard porphyry. Three ft per day are being made in the joint drift 2150 level to connect with tbs joint winzs, the material encountered being porphyry.

SIERRA NEVADA.—The sump at the bottom of the east sbaft has been completed and a drift started on the 2200 level to meet that comiug north from the incline. It is now 60 ft below the 2300 level. The north drift, 2200 level, is still in soft grouud, the face 390 ft from the north crosscut. Good progress is being made in the upraise from tbe 1700 level to connect with tbe North Con. Virginia shaft.

GOULD & CURRY.—Repairs last week stopped developments, but work is now making usual progress. The winze on the Savage line is being sunk from the 1900 level to the 2000 level, and crosscuts east are being run joint with the Best & Belcher on both the 1700 and 1900 levels. The Osbiston shaft is still encountering a heavy flow of water, the pumps raising 30 miners' inches.

NORTH BONANZA AND FLOWERY.—Ths water tank at the 300 level of the joint shaft is ready to calk and the rock chute is completed. An engine of sufficient capacity to sink 2,000 ft was bought yesterday, and will soon be placed in position. The north drift is following the ledge at the rate of six ft per day. There is no water there to hinder operations.

BELCHER.—The main incline is now 125 ft below the 2560 level. The south drift on the 2560 level is averaging seven ft per day.

UTAH.—Repairs to the incline during tbe past week have somewhat delayed operations at other points. A water tank has been put in near the bottom of the incline, so as to be in readiness when the standing pumps are in place.

OVERMAN.—The winze from the 1600 lsvel is still in porpbyry containing streaks of quartz, which are increasing in size with depth. The north drift, 1600 level, is in soft vein matter from which some water seeps in. Tbe O & C shaft is down 470 ft in good working ground.

YELLOW JACKET.—Put in the new air-compressor. The engine of the compressor is now on its bed. The work of putting in the air pipes is progressing well.

HALE & NORCROSS.—The winze from the east drift, 2000 level, is nearing the 2100 level. The pumps are all holding ths water below the 2000 level.

CROWN POINT.—The north drift, 2500 level, is still skirting the ore vein, laying it bare ready for crosscutting.

BULLION.—An airwry is being cut in the crosscut, 1340 level, for better ventilation. The formation encountered is still porphyry and quartz. The foundation stones for the new air compressor are being laid, and the shaft is undergoing repairs at the 500 station.

BEST & BELCHER.—The general overbauling at tbe Gould & Curry last week interfered with work in tbe mine somewhat, but operations are now going on as usual. A joint drift is being run with Con. Virginia west on the 1700 levsl and joint crosscuts east with the Gould & Curry on botb the 1700 and 1000 levsls.

JULIA CON.—Pumping to the surface and into the Sutro Tunnel. The sprung and twisted reel shaft has been replaced by a new ons. Tho bailing tanks have been taken out of the shaft. Therc has been a good down current of air again given to the north compartment of the sbaft. The 2000 level has not yet been freed from water.

MT. HOON & VANCOUVER.—Last evening tho 1400 level of the Mint shaft was drained and the water was taken from the sump 25 ft below that level.

WARD.—Work in the east crosscut, 800 level, will be resumed the last of this week. The men are digging tbe trench for the water pipe from the tank to the works. The new engine will start as soon as tbe new skeet is ready for use.

NORTH CON. VIRGINIA.—Tbe shaft is still encountering the hardest kind of rock, but making three ft per day. It will connect with the upraise from the 1700 level of the Sierra Nevada in about 10 days.

UNION CON.—Tbc work of enlarging and retimbering the north drift, 1450 level, connecting with the Sierra Nevada, continues. Ths joint Mexican winze from the 1000 level is down 278 st on the slope, in hard blasting porpbyry.

CROLLAR-COMBINATION SHAFT.—The work of putting in the 6-inch pipe for the air compressor has been completed, and the compressor itself is being put in place as fast as possible.

JUSTICE.—At the old Waller Defeat ground, three shifts of seven men each ars employed extracting ore which is being worked at the Pappoose mill. The capacity of this mill is 20 tons per day, and it is kept running.

CON. IMPERIAL.—South drift, 2000 level, to connect with the old workings of the Yellow Jackst, is in 50 ft, and in fine looking quartz.

LADY BRYAN.—Sinking below the 600 level as usual. The drifts north and south on this level are still being driven ahead and making good progress. The [illegible] to the south is in very fine looking quartz, but of low grade. The one north is outside tbe quartz for [illegible], but is in the vein.

LEVIATHAN.—The face of the north [illegible] the

The Troublesome Teredo.

[Written for the PRESS by W. A. LAWSON.]

His Habits and Associates.

The teredo, or as it is more commonly called, the ship-worm, was formerly supposed to be a native of the tropical seas and to have been carried by ships into the colder waters, as it is now found along the northern coasts of Europe and America, and is in many places exceedingly destructive. But this belief has been recently proved to be erroneous. In the course of some excavations made at Belfast, the trunks of a tree, entirely riddled by the teredo, was found twelve feet below the surface, in strata of an age long previous to the days of navigation, and fossil woods, once the home of the teredo, have been found in many other localities, at considerable depths; facts which prove that the teredo has inhabited from a remote period the waters of the temperate zone. The most familiar species is the *teredo navalis*, which has always been met with in the Bay of San Francisco.

The teredo has of late years been the subject of much study by some naturalists, and much thought has been expended and many experiments made in the attempt to devise means of protection from its ravages. In waters where this pest abounds, a solid stick of timber, unprotected, becomes completely honeycombed in a year or two and may be broken by the slightest shock.

At Norfolk Navy Yard, a piece of wood, which had been immersed in sea-water only eight days, was penetrated by a teredo to the depth of one-eighth of an inch. They are so small when they enter the wood as to be almost invisible to the naked eye. The worm, as it may be called for convenience, enters at right angles to the grain until fairly into the wood, and afterwards excavates in a direction parallel with the fibers, diverging only to avoid some obstruction in its path. When full grown they measure from one to two and a half feet in length. It makes its home in the wood and derives its food entirely from the water. As it grows it constantly extends its cell or gallery, but avoids an intrusion into the lodging of another.

The teredo's method of perforation has been a matter of dispute, but late researches have shown that its excavations are accomplished by means of a partial rotary motion imparted to its bivalve shell. This shell is attached to or forms part of the larger or superior extremity of the teredo, which does all the boring. Through the inferior extremity which is constantly protruded into the sea, the teredo sucks up and circulates through its system, by means of syphon tubes, a constant current of water, containing the infusoria upon which it lives. It is hardly possible to apply the terms head and tail to a mollusk which bores at one end and feeds at the other. A muscular organ, called by naturalists its foot, and by which it holds itself firmly against the head of its gallery, while boring, projects from between the valves of the shell at that end of the teredo, which one would naturally call the head. The worm has a complicated muscular system for a creature whose whole life is devoted to the making of a hole and to filling it with its own growth. The cells made by it are commonly from one-quarter to one-third of an inch in diameter at the larger end, gradually increasing in size from the minute orifice by which its entrance was effected. Thus the teredo makes its home a prison that it never leaves. And so a timber whose surface may show no sign of its depredations may be completely riddled within. At first sight, the teredo would appear to have accomplished the problem of pulling its hole in after it.

Another timber-worm, still more destructive in its action, is of the order *isopoda* and genus *limnoria*. The best known species is the *L. terebrans*, much smaller than the teredo, being at maturity only from one-fifth to one-half of an inch in length. The limnoria penetrates at right angles to the line of the fibers and pursues its course across the grain of the wood. Countless numbers of these limnoria attacking a pile from all sides, eat almost into the heart of the timber, so that it may be broken by a slight lateral strain. T. J. Arnold, Engineer to the Harbor Commissioners, in his report made to the Board in February, 1873, states that the limnoria had only recently made its appearance in our waters. Since which time it has become as troublesome as the teredo.

Still another timber destroyer now inhabits our waters. Mr. J. R. Scupham, Asst. Engineer of the C. P. R. R., discovered it about two years ago in San Francisco bay, and it seems to be fast increasing in numbers. This last arrival is a crustacean of the genus *chilura*, and species *terebrans*. It is much larger than the limnoria, and attacks timber in the same way, by cutting across the grain of the wood. From the fact that it enters the piles just above the mud, it may do great injury before its presence is known or even suspected. What its fate may be in our waters it is impossible to determine. It is supposed to have been brought here by shipping from Australian ports.

Neither the teredo nor the limnoria will thrive in brackish waters. They require sea water, free from all impurities, and avoid places where the water is contaminated by the discharge from sewers. They do not attack piles while the bark remains on, but wherever the timber becomes exposed there they enter; with this difference: the teredo always penetrates from below low-water mark, while the limnoria most frequently attacks just below the line of high water. It is thought that the latter likes to take the sea air between tides. The Commissioners state that in the harbor of San Francisco the bark protects the piles for about two years, and that in the course of five years more they have to be renewed.

In the archives of Holland, is preserved a paper by Dr. E. H. Von Baumhauer (of which a translation appeared in the *Popular Science Monthly* for August and September, 1878,) containing a description of many methods for the preservation of timber, that were tested in Holland, under the direction of the Royal Academy of Sciences of Amsterdam. Of these methods were two classes: coatings applied to the surface of wood, or modifications of the surface itself; and impregnation of wood with different substances which modify the interior as well as the surface of the wood. Of the first class, eight processes were submitted to the Commission, including metallic paint; mixture of coal tar, resin and sulphur, applied hot; paraffine varnish; coal tar, applied cold in successive layers; turpentine; linseed oil; color paints, and charring the surface of the wood. Specimens of wood treated by these processes were placed in sea water in May, 1869. An examination made six months afterwards convinced the Commission that none of them were effective, and that no mere exterior application could guarantee protection. Of methods of impregnating wood, they examined the following: Sulphate of copper, green vitriol, acetate of lead, silicate of lime, oil of peat, and oil of creosote. The only one of these that found favor with the Commission was that which employed the oil of creosote. They concluded that mere external coatings were insufficient, as they were likely to be injured by mechanical means or were dissolved by the water. As soon as the smallest surface became exposed, the teredo penetrated. Impregnation with soluble salts is ineffective, because they are dissolved by the action of the sea water. In employing the oil of creosote, it is necessary that it be of good quality, the impregnation thorough, and such woods be used as will absorb oil readily. These conclusions were confirmed by subsequent experiments of Belgian and French engineers.

It is to be regretted that the Holland Commission made no experiments with petroleum. It was recommended to the Commission, but on account of its high price at the time, it was thought useless to try it. This substance, now so cheap (selling in Pennsylvania at about two and a half cents per gallon) and abundant in California, might make a most effective preservative if properly used. Some of the heavy California oil, which thickens on being exposed, and changes into a substance called maltha, (allied to asphaltum), would seem well suited to the purpose. Whatever process is used, it appears to be essential that the sap be thoroughly expelled from the wood, and the albumen that remains be coagulated by heat before the impregnation is effected.

The cost of the oil of creosote will probably prevent its general use for this purpose. It is obtained by the distillation of coal tar, and is sold in the Eastern market at about six cents per gallon. It is not manufactured here, and the crude coal tar commands a higher price in this market. One gallon of creosote oil is required for each cubic foot of wood. Various preservative methods employing creosote have been tried in San Francisco, called respectively, the Seely, Robbins, and Woods processes, but none have been satisfactory to the Harbor Commissioners.

A San Francisco company propose to erect works for the preservation of timber by the Thilmany process, which employs sulphate of copper, with the addition of chloride of barium, forming sulphate of baryta, which is claimed to be insoluble in water. Of all the processes tested by our Harbor Commissioners, this is the only one which has so far proved efficacious. They have a piece of Michigan pine which was treated by the Thilmany process, and placed in the water of the Bay, beside a piece of the same wood, unprotected. After an exposure of two years, the pieces were taken up, and the one so treated found intact, while the other was completely riddled by the teredo. The Commissioners are not sure that the process would be efficacious with the Oregon fir, in use in our waters. They are giving some other pieces of wood, treated by the Thilmany process, a longer test.

San Francisco, March, 1879.

PACIFIC COAST EXCHANGE.—A corporation, says the New York *Evening Post*, has been recently organized in that city for the general representation here of Pacific Coast interests. It is called the Pacific Coast Exchange. The intention is to have in this Exchange a collection of specimens of all the products of California, Oregon and Nevada; also, offices for all the railroad companies connected with those States, and for other corporations interested in that territory. Pacific Coast newspapers are to be kept on file, and the rooms are, generally, to be the headquarters of the business of that section in New York. Negotiations, by the corporation, are in progress for the lease of No. 734 Broadway, a brick building, 25x137½, with ornamental iron front, and comprising five stories, with a basement and sub-basement, for the above purpose.

Fish Farming.

Our State has made no small progress, during the year, in stocking public and private waters with fish, and those who breed carp say that their stock has been much reduced by the demands of new water farmers. The work of our fish commission is already bearing fruit in the large catch of desirable fish introduced by them. The public and private development of our resources in this direction can well go on, until ponds and rivers rival adjacent fertile fields in the amounts of food they yield for the support of man. This subject is urged in all States which have energetic fish commissions at work, and the awakening to water farming as an adjunct to land farming, is quite widespread. We notice that Hon. Robert B. Roosevelt, a member of the New York State fish commission, has been addressing the New York farmers' club upon the chances for good yields from their waters as well as their fields, and some of his points are of general application. If the farmer can add to his usual crops a crop of fish, he will be benefiting his neighbors as well as himself. To do so may seem to many at first glance a difficult operation, but not half as much so as making the broad acres "laugh with a harvest" seems to the inexperienced. Fish farming has its rules and limits, precisely as land farming has, but is simpler and far more productive. From a single mature fish millions of young may be produced. A sturgeon contains nearly ten millions of eggs, cod and herring millions, shad hundreds of thousands, and even trout and bass several thousands. With good management these can all be hatched, and in some cases in very few days. Once hatched, and fish provide for themselves; they need no food or care, they convert worthless insects or waste water-grasses into human food. The trout or bass from a farmer's pond costs him nothing but the trouble of catching, and compares in excellence on his table with his best poultry, to say nothing of pork that has been fed twice a day for months. The only loss of time or labor is in the catching, and to reduce that it is only necessary to make the fish abundant.

There is a fish, we well remember to have pulled it from New York waters, which Mr. Roosevelt pronounces especially fitted for farmers' ponds. It is the fresh-water bass, and, if we mistake not, our California commissioners have already introduced it in this State. If so, it may, in course of time, be available for farmers' ponds. Mr. Roosevelt says it is possibly even more valuable than the trout for the farmer's use. It is not so exacting in the character of the water in which it will live, and will grow more rapidly; more important still, it needs no culture or care whatever, or any time. The parents, which are fairly prolific, lay their eggs in a sort of nest and watch over them till they are hatched. Bass have never failed to increase rapidly where they have been introduced, and they are suited to almost any pond. These are especially the fish to be used where water farming is to be combined with land farming in the simplest and easiest way. Nothing is required but to place a few pair of mature fish, which can be easily transported in any water they are expected to populate, and they will attend to the rest themselves. They can hold their own with any other species, even against the dreaded pickerel; they increase rapidly and grow quickly, and as human food they are excellent.

It is hardly the right season of the year now to make fish ponds, but it is well to begin early with the plans and estimates, so that all may be ready when the harvest is secured, to shape the dry basin into a pond, to be filled when next winter's rains swell the streams.

Sonora Anthracite Coal.

About a year ago, a large deposit of excellent anthracite coal was discovered near Barranca, Sonora, and it has been used with satisfaction at the Barranca mill, which is engaged in the pulverization of ores. The mine is six and a half miles from the mill, and in the vicinity of several mining towns. The approaches from Guaymas, from which it is distant 125 miles, are almost entirely level, and there is but a moderate grade from San Antonio. The dip of the coal-beds approximates to 10 degrees, the course being northeast. So far, an incline 70 feet long has been excavated, all the way in anthracite perfectly free from slate. The roof is composed of excellent fire-clay. It is considered by the engineer of the Barranca mill superior to Pennsylvania anthracite, and he testifies that it gives no clinkers. Gen. W. S. Rosecrans reports on a specimen brought to San Francisco that the specific gravity is 1.77, whereas that of Pennsylvania anthracite is about 1.5. Mr. W. Bruckner, M. E., states that an analysis of the coal shows it to have but 2½% ash. He thinks this Sonora anthracite belongs to a much older formation than the anthracite coal of New Mexico, described by him in Prof. R. W. Raymond's report to the Secretary of the Treasury in 1870; in fact, he thinks it is sub-carboniferous, or older than the Pennsylvania deposits. We have no particulars of the grounds upon which this opinion is based, but the appearance of the coal does not apparently confirm it.—*Arizona Sentinel.*

Tribute to American Explorers.

The following tribute to American explorers is from the pen of Prof. T. C. Archer, Director of the Museum of Science and Art, Edinburg, and Centennial Commissioner from Great Britain:

There is nothing in the history of the human race more remarkable than the rapidity with which the wilds of Western America have been explored and added to the domains of civilized man. Middle-aged men can remember the first great rush to the Californian gold diggings, and the export from this country of iron houses for the shelter of the miners where now a splendid and populous city exists, and is the resort of travelers from all parts of the world; whilst in a marvelously small space of time the great State of which that city is the capital, has become one of the most fertile and wealthy in the great Republic, and is now connected with the eastern shores of the continent by 2,000 miles of railway. The spirit of enterprise, no doubt, has had much to do with this wonderful progress; but the far-sighted and liberal spirit of the United States Government has made the task comparatively easy. The careful but energetic surveys, both geographical and geological, which have been working for years past, have made the best routes known, and, in fact, have opened up the heart of the country, and made the most distant and the most desert parts accessible. Fortunately for the Government and the country, men of the greatest fitness for the task were selected, and the great extent of the work they have done proves their industry, as well as the nature of it shows their great abilities. The Atlas of Colorado and portions of adjacent territory, is one of the most masterly works in chartography which any country has produced, and its compact arrangement will make it a welcome addition to every library. It consists of 20 double folio sheets, of which two are filled with cleverly outlined panoramic views of the country surveyed, and two others give the sections of the same geologically colored. Twelve are devoted to the six divisions into which Colorado is divided, one-half of them giving the topographical and the other half the geological features of the country. There is, in addition, a map showing the triangulation of the country, another showing the natural drainage, an economic map indicating the agricultural, pasture and forest lands, and the locality of coal-bearing and metalliferous strata. Of the execution of these maps it is impossible to speak too highly. They have been produced by the talented and indefatigable chief of the surveys, Prof. F. V. Hayden, and are a part of a series of the reports and transactions of the Survey Department, some of which we hope to draw attention to from time to time, as they can generally be consulted in public libraries, to which the United States Government extends its liberality.

A Joint Resolution of Thanks to Dr. Hayden.

The following joint resolution of thanks to Prof. Hayden and his assistants for their "Accurate and Comprehensive Survey of Colorado," was recently adopted by the Colorado Legislature.

WHEREAS, The geological and geographical survey of the Territories of the United States, made under the general government, has been completed for the area embracing the State of Colorado; and

WHEREAS, The publication of the reports, views and maps of this survey form a collection invaluable alike for the advancement of science and the development of the mining and agricultural interests of this State.

Resolved, That the thanks of this Assembly are hereby tendered to Dr. F. V. Hayden, United States Geologist in charge of the survey, and his assistants for the merit of their contributions to the successful achievement of this great work.

Resolved, That a copy of this resolution engrossed on parchment shall be presented to Dr. F. V. Hayden.

A REPORT ON THE DARIEN CANAL.—To obtain a conclusive report upon the practicability of cutting a channel through the Isthmus of Darien, a French company, with the approval of the Geographical Society of Paris and the Society of Commercial Geography, despatched a survey expedition under the leadership of Lieut. Wyse, of the French Engineers, who had already spent many years on the isthmus for a similar purpose. We learn from a foreign exchange that, after two years' surveying this officer has lately returned, bringing with him the completest surveys that have yet been made of six of the most promising canal routes, one of which passes through Nicaragua, while the other five are in Columbia, where the lowest gradients and the shortest routes occur. Although the level of the two oceans differs but slightly, the nature of the intervening country is such as to render it impossible, according to Lieut. Wyse, to dispense with locks or tunneling, or both, on any of the routes he has surveyed.

COMPRESSING BRAN.—We recently referred to some successful experiments in compressing flour. We now learn that some Minneapolis millers are experimenting with machinery for compressing bran, for the purpose of shipment to Europe. It is believed that it can be so compressed as to get as much weight into a given package as the same would hold of flour.

PHOSPHIDE OF CALCIUM on becoming wet will give off spontaneously combustible phosphoreted hydrogen, thus emitting light. This is the principal ingredient used in the distress and guiding signals thrown into the water from a sinking ship, principally to guide those in the water to the boats.

Central American Telegraphs and Railways.

The telegraph lines of Nicaragua and Hnnduras have lately been joined together by the completion of the missing link in Nicaragua territory between Chicbigalpa and the boundary between the two conntries at Rio Negro. Telegraphic communicatinn is thus cnmplete throughout the four Republics of Costa Rica, Nicaragua, Guatemala and Honduras, from San Juan del Sur to Mexico. A moderate tariff is tn be enforced for through uiessages.

In Houduras further extensions of the telegraph system are beiug made, aud 150 miles of new wire are iu course nf completion, in addition to the 500 already opened.

This republic is giving further evidence of its desire to advance hy organizing an "exhibition" on a modest scale, which was open for a short period towards tho end of last year. Happy augury for the bondholders! Honduras bonds at £3 per £100 boud! Honduras having an exhibition!

The Government of Costa Rica is encouragiug the introduction of immigrants for the purpose of constructing railways on the Atlantic coast, and improving the communication between the terminus at Pacuore aud the interior by meaus of carriage roads. The carriage road from San Jose to Las Palmas and the river Sucio is being rapidly pressed forward. Of the total length of about 80 miles only 29 miles are required to complete the work, by which a saving of 20 miles will he effected, compared with the old apology for a road via Cartago. A new port is being constructed nn the Pacific coast, at Cocos, on the Bay of Calebras. The erection of public offices and other works has been ordered by the government, and the port will he, for the present at least, entirely free from all harbor, light, anchorage and nther dues.—*British Trade Journal.*

Prehistoric Remains.—Georgo Carr and others, mining on Lynx creek, says the *Arizona Miner*, have unearthed a bonanza of human remains and curiosities consisting of jaw-hones, ollas, beads, stone-knives, metat-stones, etc. The beads are interspersed with curiously wrought pendants, or flat pieces of blue and green stones of very diminutive size, each punched or drilled in one edge or corner. The heads are of irregular sizes, hut all quite small, some black, some white, and otbers of various shapes and colors, and when strung as they are now, hy the finders, form a very curious and unique specimen of the ornaments, or perhaps charms of a hygone and unknown age. Perhaps the straugest and most interesting phenomenon of the collection is a jaw-bone, which in shape, size and every other feature except that it has not, and evidently never had but three or four teeth, and they directly in front, is that of a human jaw. Whether its possessor in his lifetime was a grass-eater, which after biting it off he swallowed whole and afterwards chewed his cud, or whether this is an exceptional case, and a deformity, some one more learned in anatomy tban we, will have to determine. The mctat-stones are of malpice and very small. These relics were found on the top of the hard cement or false bedrock, some four feet from the surface of the ground.

A Petrified Human Hand.—A curiosity which astonished scientists and puzzled them to account for is now on exhibition in Gould's cahinet at Mill City. It is a perfectly formed hand, which, apparently, helonged to a hoy about 14 years of age. The hand is open, the fingers heing slightly bent toward the palm, on which the thumb rests. The hack of the hand seems tn have been crushed or decomposed hefore it was petrified, hut the palm, thumh and fingers are perfect. We were informed that it was found at the sulphur beds near Rabbit Hole, hy one of the men employed in shoveling crude sulphur into the refining retort, and is supposed to have heen imhedded in the sulphur bank for ages. The fingers are comparatively short, a fact which indicates that it did not belong to an Indian, as the red men's fingers are generally longer than those of the white; hut the thumb is rather longer than the average. Tn wbat race the owner of the hand helonged, and how and when it was imhedded in the sulphur, will probahly remain unknown, nnless some scientist should investigate the hand and the sulphur bank where it was found and explain these mysteries.— *Winnemucca (Nev.), Silver State.*

The New Goloid Dollar.—The first specimen of the metric gold double eagle on the golnid principle, of the full value of $20, coined at the Philadelphia United States Mint, has heen received at the Treasury department. It is a heautiful coin of the size of the old douhle eagle, having a very rich hue. The design of the ohverse side is a head of Liherty surmounted hy 13 stars, hetween which is the metric inscription "30g. 1.5s. 3.5c. 35 grains," helow which is 1879. On the reverse is the double eagle, surmounted by the words "United States of America" and a circlet of 13 stars emhlazoned. Within the circlet is the Latin inscription "Deo est Gloria," in a scroll held hy the eagle the words "E Plurihus Unum," meaning, when translated, "The United States of America—to God is the Glory—of many one." Beneath this the words "twenty dollars." The coin has heen handed over to A. H. Stephens, Chairman of the Committee on Coinage. It is patented hy William Wheeler Huhhell, and is the companion coin of the goloid dollar.

Useful Information.

Fresh and Stale Bread.

The celebrated French chemist, M. Bousingault, has recently investigated the nature of the change which bread undergoes when it becomes stale. Up to the present time this has not been well understood.

A circular loaf, 12 inches in diameter and six inches thick, was taken from an oven heated to 240° Reaumer, and a thermometer immediately forced three inches into it. The thermometer indicated 78° R. (207.5 F.) The loaf was then taken to a room at a temperature of 15° R. (66° F.), and was found to weigh seven and a half pounds. In 12 hours the temperature of the loaf sank to 19° R. (73° F.), in 24 hours to 15° (66° F.), and in 36 hours to 14° (63.5° F.). In the first 48 hours it lost only two ounces in weight. After six days the loaf was again put in the oven, and when the thermometer indicated that its temperature had risen to 55°R. (156° F.), it was cut, and was found to be as fresh, and to possess the same qualities, as if it had been taken out of the oven for the first time; but it had now lost 12 ounces in weight. Experiments were also made on slices of the loaf with similar results, proving that new bread differs from old, not hy containing a larger proportion of water, hut hy a peculiar molecular condition. This commences and continues to change during cooling, but by again heating the bread to a certain temperature it is restored to its original state. It is this mechanical state which makes new bread less digestible than old. The former is so soft, elastic, and glutinous in all its parts that ordinary mastication fails to reduce it to a sufficiently divided condition. It forms itself into hard balls, which are almost unaffected by the gastric juice. These halls often remain in the stomach, and, like foreign hodies, irritate and discommode it, inducing all sorts of unpleasant feelings.

Electro-Bronzing on iron has heen brought to a high state of perfection hy the Philadelphia Smelting Company. This company has taken out patents covering the process for putting on iron a durable electro-bronze finish, which is claimed to possess the beauty aud finish of real bronze at a very much lower cost, and to be wholly unaffected in color, etc., hy the action of the atmosphere. The following is the process adopted: The articles to he bronzed are first put in a bath of paraffine, which stops further oxidation; they are then coated with a metallic substance and subjected to the electro-bronzing bath, after which they are treated with a peculiar protecting varnish, and are then ready for use. The metallic substance with which the articles are coated is called "Deoxidized Bronze," and is claimed to possess in a remarkable degree all those features for which alloys are valuable. It is composed entirely of copper and tin, the peculiarities in the resulting texture being entirely due to to the flux used and the method of treatment. It is said to possess superior malleability, approaching gold alloys in this respect, while its tenacity and solidity are very great. Specimens eight inches long admit of heing douhled up without apparent injury to the structure. It flows readily, is easily haudled by ordinary workmeu, and is capable of reworking from old scrap. It is also receptive of a high, smooth finish, wears well, and is largely used for machine journals, car bearings, and other purposes of a similar nature, where a durahle anti-friction metal is required.

New Varnish for Foundry Patterns.—A varnish for foundry patterns and machinery has been patented in Germany, which dries as soon as put on, gives the patterns a smooth surface, thus insuring an easy slip out of the mold, and prevents the patterns from warping, shrinking or swelling, as it is perfectly impervious to moisture. This varnish is prepared as follows: Place in a vessel 50 pounds of shellac, 10 pounds of manilla copal, and 10 pounds of Zanguebar cópal, and heat it by the external application of steam for four or six hours, stirring it in the meantime constantly. Then add 150 parts of the finest potato spirit, and heat the whole during four hours to 190 deg. Fah. This liquid is then dyed by the addition of orange color, and can he used for painting the patterns. When used for painting and glazing machinery, the varnish may consist of 35 pounds of shellac, five pounds of cocoriel copal, 10 pounds of Zanguebar copal, aud 150 pounds of spirit. Similar varnish to the ahove is used quite extensively hy pattern-makers in this country, and much of the superior appearance of American castings is duo to its use.

To Cast Brass Solid.—The metal should not he run auy hotter than is necessary to insure sharp castings. The most probable cause of the honey-combings of castings is that the air can not get out of the way; and there ought to be proper vents made for it from the highest parts of the mold; the metal should he run in near or at the hottom of the mold. If about one pound of lead he added to every 16 pounds of old hrass, when just at the melting point, solid good hrasses will be the result. In melting old brass, the zinc, or lead, contained in it (when fluid) oxidizes freely, consequently the proportions of the metals are altered, and require an addition similar to the ahove. If the hrass has not heen recast, a little less lead will do, hut if recast several times, it may take the full quantity.

Rearing Sponges by Artificial Means.

During the past few years, Dr. Oscar Schmidt, Professor of Zoology, at the University of Gratz, and a well-known authority on sponges, has employed several weeks of the early summer in artificially producing and rearing the bath sponge. His labors have met with such success that his system has been adopted by the Austrian government, and is now carried out on the coast of Dalmatia. It has for some time been a well-known fact that several families of zoophytes have such great powers of reproduction, that a portion of one will grow aud form on an entire new body. Dr. Schmidt has taken advantage of this property, his process being to cut the sponge iuto pieces, fasten each portion to a pile, and immerse it in the sea. The pieces then grow, and eventually from each one a spherical sponge is obtained. According to the estimates of Dr. Schmidt, a small piece of sponge at the end of three years will represent a value of about 10 cents. The total cost of raising 4,000 sponges, including the interest on the expended capital for three years, is estimated at $45, and the income at about $80, leaving, therefore, a net profit of $35. There is no doubt that the practice of this new branch of industry will prove a source of considerable benefit to the inhabitants of the Idrian and Dalmatian coasts.

Waterproof Soles.—Waterproof soles which are either inserted into ordinary leather soles nr laid into the boot are prepared in Germany as follows: A mixture is prepared, consisting of 60 parts of rosin, 80 parts of tallow, 5 parts of wax, and 5 parts of turpentine. In this mixture linen is soaked. This is therehy rendered watertight. The sheet of linen is then united to a sheet of wool hy being passed through rollers. On the linen side the sole is now covered with a solution of glue, to prevent the resinous surface from sticking to the stockings and shoes in walking.

How to Distinguish Diamonds.—M. Rabinet, of the French Academy of Sciences, gives the following test for distinguishing colnrless gems from diamonds. If a person looks through a transparent stone at any small object, such as the point of a needle, nr a little hole in a card, and sees two small points, or two small holes, the stone is not a diamond. All white colorless gems, with tho exception of the diamond, make the object examined appear douhle; in other words, double refraction whenever exhibited by a stone, is conclusive proof that it is not a diamond.

Good Health.

"Modus Operandi" of Skin Grafting.

Pinch up a small amount of the cuticle from the inside of the arm with a small pair of forceps, and divide it with a small pair of concave scissors, being careful not to draw blood, and get the slip free from adipose tissue; insert this piece of skin into the granulations about one inch from the margin of the sore, and repeat in a similar manner until you have slips within an inch of one another all over the ahrasion. The size of tho piece of cuticle is uot so material; the object to be attained is to have it grow, and it can't take root unless it be buried into the ulcer. A piece of skin the size of a pin's head is large enough. When the grafts are all inserted, dress the sore with au artificial scah, made nf *adeps porci*, nine ounces, and thickened into a paste with English prepared chalk, twelve ounces, and spread over the sore and margins, retaining it there with a roller nr adhesive plaster. Let this dressing remain on for three days, then redress by removing this artificial scab, and wipe the sore with a soft clotb. Never use any water in dressing old sores, for it seems to make them take on those horrible nocturnal neuralgias the night following. Then remove your paste carefully and wipe dry; wherever a slip has taken you will notice a small depression at that point, and if you think advisable you can insert other grafts, and dress as before, and so on, until cicatrization is perfected.

How Long to Continue Transplanting.

Until the sore is studded full of grafts, and the ulcer, to all appearance, about well. If the sore is on the lower limb, quietude in the recumhent posture should he observed, and the leg elevated, as any pressure upon the ulcer at this time would cause most serious interference with the new granulations, as well as destroy the newly formed cuticle within the sore, which resemhles so many small islands in a hody of water; these little islands of skin will meet the skin from either side, and therehy hridge the ahrasion over. By carefully watching at this stage the new skin will become permanent, so that your patient may he allowed to go about. If the sore is on an upper extremity, the patient can have more liherty to go round. As regards the dietetic plan in these cases, as a general thing, the regimen should he articles of diet containing fat nitrogenized, and phosphatic combinations, together with milk and eggs. Stimulants should be avoided.—*Medical and Surgical Reporter.*

Antimony in the System.—It has lately heen estahlished that antimony, unless taken in extremely large doses, will quickly eliminate itself from the system.

The Progress of Dentistry.

Some hopeful results in the practice of dental grafting have been recently brought tn the notice of the French Academy by MM. David and Magitot. Two principal forms of such grafting are distinguished—tbe graft by restitution and the graft hy borrowing. In the former a tooth is reimplanted, after having beeu extracted with a view to certain operations, which would be impracticable in the mouth. M. David has adopted this method for rectifying the direction of teeth, for treatment of carics in the extracted tooth, for stopping and also for facilitating operation on another tooth, or in another part of the mouth. The consolidatiou of the tooth restored to its socket occurs generally on the tenth or twelfth day. In the graft by borrowing, a sound tooth may be substituted for a decayed nne. As regards transplantation from the lower animals, of course no zoological species has hitherto furnished teeth similar to ours in form, dimensions, color, etc. Still, sound roots (from a lower animal) may bo substituted for bad ones, and may serve as a solid hase for pivoted artificial teeth. Tbe transplantation from nne human heing to another would generally involve objectionable mutilation. But sound teeth may bo utilized for the graft when their extraction has become otherwise necessary. A tooth may he transposed from one part of the mouth to another. Practicing the dental graft by restitution, M. Magitot has operated in 62 cases, and 57 of these have been decided cures — a success amounting to 92%.—*Scientific American.*

The History of Diphtheria.—It is often said that diphtheria is of modern origin, a penalty for the unsauitary condition of modern civilization. Dr. Mackenzie, senior physician to the Hospital for Throat and Chest Diseases, in London, finds the disease to he a very ancient one. The first description of it occurs in the writings of an Indian physician, a contemporary of Pythagoras. He next identifies it with "askara," a fatal epidemic frequently mentioned in the Talmud. In the 17th century diphtheria was widely prevalent in Europe, and extensively fatal. In 1802 Dr. Cullen, of Edinburgh, seems to have described the disease under the name of *cynanche trachealis;* and in 1826 Bretonneau's classical work appeared. "After this," writes Dr. Mackenzie, "the disease seems to have passed from the minds of English physicians and its very existence to have been almost forgotten." From such forgetfulness the medical profession was thoroughly aroused hy the great epidemic of the years 1858-9, since which time diphtheria has not appeared in England with anything like the same malignancy.

Recuperating the Brain.—An intelligent writer on this subject thinks the use of stimulants to fortify tho exhausted brain an unwise measure. Tbe best possible thing, he says, for a man to do when he feels too weak to carry anything through is to go to bed and sleep as long as he can. This is the only recuperation of the brain power, the only actual recuperation of brain force; because during sleep the brain is in a state of rest, in a condition to receive appropriate particles of nutriment from the blood, which take the place of those which have been consumed hy previous labor, since the very act of thinking burns up solid particles, as every turn of the wheel or screw of the steamer is the result of consumption hy fire of the fuel in the furnace. The supply of consumed brain substance can only he had from nutritive particles in the blood, which were obtained from the food eaten previously, and the brain is so constituted tbat it can best receive and appropriate to itself those nutritive particles during the state of rest, of quietness and stillness of sleep.

Rest for Headaches.—Dr. Day says, in a late lecture: Whatever he the plan of treatment decided upon, rest is the first principle to inculcate in every severe headache. Rest, which the husy man and the anxious mother cannot obtain so long as they can manage to keep about, is one of the first remedies for every headache, and we should never cease to enforce it. The hrain, when excited, as much needs quiet and repose as a fractured limh or an inflamed eye, and it is ohvious that the chances of shortening the seizure and arresting the pain will depend on our power to have this carried out effectually. It is a practical lesson to he kept steadily in view, in that there may lurk behind a simple headache some lesion of unknown magnitude which may remain stationary if quietude can he maintained. There is a point worth attending to in the treatment of all headaches. See that the head it elevated at night, and the pillow hard; for, if it he soft, the head sinks into it and hecomes hot, which with some people is enough to provoke an attack in the morning if sleep has heen long and heavy.

Hot Water vs. Fever Germs.—According to Dr. Richardson, hot water at 120° Fah. will kill typhus germs, and soap acts as a poison to them. The remedy against typhus, then, is to he found in every household, and more's the pity if it he not applied. Considering the deadly nature of this fever, and the fact that 50,000 typhus germs will thrive in a space no bigger than a pin's head, it is clear, the *Christian at Work* thinks, that in such a matter, a quart of prevention is worth several hogsheads of cure.

The Week.

The termination of the mining debris case has caused much quiet talk among miuing men, for in view of the decision rendered, unless new means of disposing of tailings are inveuted, hydraulic mining iu California must virtually cease. An interesting review of the subject will he found in another column.

The late heavy rains bave occasioned local floods in many parts of the State. Napa City was partially under water, and some regions of Sonoma county have heen overflowed. Humboldt reports large tracts submerged, and along the line of railroad nortb of Sacramento, the breaks and washouts have heeu so serious and extensive as to prevent travel and traffic for some days. The improved outlook for the season is leading to hrisker movement in the shipment of wheat, and quite a number of the idle merchant vessels lying iu the harhor have been put under charter since the last rain. The Darien sbip canal project bas again heen revived, and an international consultation as to its feasibility will soon be held at Paris.

Europe seems out of sorts. Bismarck is in bad temper over the failure of his Parliamentary restriction bill, and tbreatens to dissolve the Reichstag altogether. France is still exercised over ministerial troubles and the discovery of treasonable plots by the former Rochebonet ministry against the republic. Eugland suffers from want among the laboring classes, Russia is still sick with the plague, and Hungary is devastated by an extensive flood, which has destroyed many lives and a large amount of property.

Temporary Openings in the Mines.

By reason of the frequent and heavy rains that have fallen the past two weeks, the rivers and gulches throughout the mining districts of California are everywhere running full of water. Even the small gulches, that in ordiuary seasons remain dry or nearly so, througb the winter, are, at this time, swollen into rivulets. With this free and abundant supply of water, it is possible now to profitably work many gold-hearing localities that can only be worked under the conditions that at present exist. These localities, which are neither few nor of limited extent, can he found in every mining county along the main gold helt of the State. They bave not, as a general thing, heen reduced to ownership, and are, therefore, open to occupancy hy whoever may choose to take them up. As the city is full of idle men, and men glad to work for a dollar a day, these unoccupied and unclaimed diggings would seem to bold out good inducements for this class to go and try their hands at working them. It is an easy matter to reach these points, unless the extreme nortbern parts of the State should he selected for the field of operations, and where they could not for the present he prosecuted with as much comfort and success as in the more central and accessible counties. The most eligihle sites for carrying on this style of mining, until such time as the winter is well over, will probahly he found along the foothills from Mariposa to Plumas, where they occur in a scattered way over a strip of country varying from 15 to 20 miles in width.

As the most of these spots have been hut little worked and in some instances not at all; tolerahly fair, and sometimes very large wages can be realized working them while the water lasts. As a good deal of snow has fallen on the mountains above, the water supply may he expected to hold out here for several months, its continuance varying greatly in different localities. The cost of out-fitting a claim iu these extemporized diggings is not large, the dirt heing run off through the ordinary hox sluice and sometimes hy ground sluicing. The miner need not here make such extensive provisiou for housing aud subsisting himself as is required where operations go on without interruption and a permanent residence is to be made in the mines. Generally, he will be able to ohtain board and lodging at some farm-house or inu near by, enabling him to dispense with the cost of a cooking outfit and the huilding of a cabiu. To work this class of placers scarcely any other tools than picks, shovels aud crowhars are required. A few hundred feet of rough timber suffices for the necessary sluices, which the miner can himself cut and nail together. If to these there he added a flask of quicksilver, with, perhaps, some pierced sheet-iron and silver-coated copper plates, he will find himself amply equipped for service, these latter being hy no means indispeusable and very often wholly superfluous.

In going into the mining districts on an errand of this kind the prospector is not apt to meet with rebuffs from old settlers. On the contrary, he is generally welcomed and directed to the most likely places for furthering his objects. Information is almost always cheerfully imparted to bim, and if he seems the right sort of a man, more substantial aid will he extended to him should he require it. Not very often does the resident population, who have more steadily paying claims or other occupations to engage their attention, care to work this class of diggings. They have, therefore, no object in concealing their whereabouts, nor preventing others from taking them up and turning them to some practical account. Not infrequently it is to their interest to have this done, the farmer, the storekeeper, and others in the neighborhood finding in these new arrivals good customers. Having found and secured a paying claim of this kind, it does not follow that the locator need, at the end of the water season, ahandon it; neither work nor occupancy in these cases heing under the local law exacted so long as there is no water for active operations. It might be well worth wbile for workingmen who are seeking employment or desirous of employing themselves, to consider this matter, making more full inquiry in regard to it and acting accordingly. Tbese are diggings in wbich small companies of four or five men could work to advantage. That number might, therefore, combine, and, though tbeir individual means be limited, he ahle to raise enough to carry them into tbe mines and set them to work on joint account. This would be much hetter than remaining in the city idle, and hetter, perhaps, in most cases than accepting the poor pittance of $1 a day, with no certainty of employment at that.

From 50,000 to 60,000 camels are used in the transportation of 10,000 troops in Northern India, and the service has occasioned great mortality among the animals.

Near Brantford, Ont., lately, an acre of ground suddenly dropped a distauce of 40 feet helow the surface, leaving the side perpendicular.

A new canal is being constructed in the northern part of Kern county. It is to be 80 feet across the bottom and 7 feet deep.

The Debris Case—Injunction Granted Against the Miners.

The first step towards reaching a final decision in the case brougbt hy the farmers of Sutter and Yuha couuties agaiust certain classes of miners, has been taken. This was an action in equity hrought nearly two years ago hy the plaintiffs in the Tenth Judicial district of this State, to restrain the hydraulic and drift miners who discharge tbeir tailings into Bear river and the various creeks and ravines tributary thereto, from further using the same for this purpose. The reasons assigned for asking this restriction were that these tailings, which consist of sand, gravel and muddy water, had already caused great injury to mucb of the bottom lands lying along and adjaceut to the several streams tbrough which they found outlet, and which injury, heing continuous, would, if suffered to go on, be likely to so increase hereafter as to render large portions of these lands worthless for the purposes of cultivation. Prior to the commencement of these proceedings, the farmers had sought relief at the hands of the State Legislature, in which hody the matter was extensively discussed but no defiuite results were reached. The parties aggrieved then formed an association aud brought this suit throughb and in the uame of one of its members, James H. Keys, who appears as the sole plaintiff therein.

The miners, making commou cause, proceeded also to form an association for resisting this suit so hrought against them; and in answering the complaint sought to have the hearing thereof transferred from Sutter, a purely agricultural, to some other county; which application having beeu denied hy Judge Keyser, occupying the bench of the Tenth Judicial district, the case came on last July before him for hearing, hoth parties bcing represented hy ahle lawyers. By the plaintiff, George Cadwalader, P. Van Clief and J. H. Craddock were employed; Samuel M. Wilson, W. C. Belcher, A. B. Dibble and James R. Byrue appearing for the defendants, the latter composed of some twenty different hydraulic and drift mining companies operating along Bear river and its tributaries, and using the same for the receptiou of their tailings.

eral weeks, a great number of witnesses were

Iu the hearing of the case, which occupied sev-examined on both sides, some of them being among the ahlest engineers and scieutists ou the coast. A large amouut of testimouy was taken, much of it hearing on the question at issue only in a general way, and not a little of the evidence adduced heing of a very conflicting character. The plaintiff showed that he was tbe owuer of and held under a United States patent 1,069 acres of rich alluvial lands lying on Bear river, some 50 miles below the mines, and upon which he had expeuded $10,000 in improvements; that on the 15th day of January, 1875, 400 acres of these lands were covered to a depth varying from three inches to three feet with the tailings or debris from the defeudant's miues, which deposit was further increased in March of the following year: that this land was thereby rendered unfit for cultivation during the year of the overflow and the succeeding year, its productive capacity heing, in fact, permanently injured: that the accumulatiou of this sediment made it necessary for him to expend further large sums in raising his fences and huildings, constructing levees, etc., and that the water in Bear river, which was formerly clear and wholesome, had by reason of the sediment so run into it heen rendered muddy, and unfit for irrigation, the use of animals and for other domestic purposes.

The testimony tending to estahlish the above points was comhatted hy that introduced on the part of the defense; who, by an equally large number of witnesses, attempted to show that the land so overflowed instead of heiug permanently injured would in the end he greatly benefited therehy; that the harm in no case was more than temporary; that the cultivation of the lands above and which had their drainage into Bear river and its confluents, had caused a large portion of the sediment complained of aud would in the future send into these receiving channels a greater amount of this sediment than would he contributed by the mines, from which the quantity contributed would hereafter be diminished rather than increased; the defendants claiming that, in any event, they were entitled to continue the use of these various outlets to their mines, basing the same on prescription and prior right, as well as upon statutory and equitable grounds.

The testimony of hotb parties having heen taken, the case was last month argued before Judge Keyser by their respective attorneys and submitted for decision, hoth as regards matters of fact and conclusions of law, this heing a case in equity and determined without a jury. The findings of the court have just beeu filed, and are to tbe effect that the grievances complained of by the plaiutiff are well founded, entitling him to tbe relief asked for, to which end the court has issued an injunction perpetually enjoining and restraining the defendants from using the hed of Bear river, or any of its tributary ravines or gulches, as a place of deposit or dump for the debris from their mines—also prohihiting them from further corrupting and fouling tbe water flowing through any of these channels, the plaintiff heing given costs of his suit.

Counsel for the defendants, upon being advised of the ahove result, immediately applied for and obtained a stay of proceedings for 30 days, during which time measures will he taken for appealing the case to the Supreme Court of California. After this trihunal shall have passed upon it, whatever their decision may be, it will, as a matter of course, he taken on writ of error to the Supreme Court of the United States for final adjndication. Meantime the miners will, no douht, execute a hond indemnifying the plaintiff for any further injury they may cause him, in case the findings of Judge Keyser should he ultimately sustained, and proceed with their mining operations as before. These operations will not for the preseut suffer even temporary intermission.

While this suit was brought nominally by a single plaintiff, and the parties made defendant were confined to a few mining companies along Bear river, the damage complained of heing comparatively trifling and restricted to a single locality, the proceeding was, at the same time, largely representative, being regarded hy both the farmers and the miners in certain districts as a test case, whereby the question here in issue was to he finally settled and disposed of. In this view of the matter, this case becomes one of interest and importance, hoth in a legal and pecuniary point of view. As the farming lands affected by this debris are not confined to the valley of Bear river, so, also, are the mining companies to he affected by this decision of Judge Keyser not confined to the defendants in this suit. A considerable extent of bottom lands along the Yuha, with some also on Feather river, have beeu covered with these mining tailings and are exposed to he further covered thereby, the same as those along Bear river. As a consequence, the mine owners whose tailings find their way into these streams are liable to he hy legal process restrained from further use of the same equally with those operating along Bear river. Hence, there arises on hoth sides a hroad community of interests in this question.

It is to he observed, however, that the interests, hoth agricultural and mining, are comparatively limited and local, the only properties and callings seriously affected heing tbose of the land and miue owners along tbe three streams mentioned. There has not heen, nor is there likely to he, much complaint on account of injury sustained hy this mining debris elsewhere in the State. This narrows down the question considerahly, raising a hope that it may he possible to adjust it in such manner that no irreparable or even very grievous injury will result to either party. Suppose, for instance, the findings of Judge Keyser should he confirmed in the court of last resort. Could not the miners, who are not asked to make restitution for past damages, combine their means and purchase theso lands, so alleged to he injured and exposed to injury, at an appraised valuation, and hy a system of levying, gradually reclaim them in whole or in part, or hold them until such time as these hottoms through the accumulations of this debris would he so raised and spread out that the streams running through them would make for themselves channels sufficiently broad and deep to carry the muddy water and sand without overflowing their hanks.

This policy, or one involviug its main features, has been adopted at least in one instance and found to work well. The Spring Valley Company, operating a large hydraulic claim at Cherokee, Butte county, after heating the plaintiff in a suit brought against them, as a means of preventing further annoyance, concluded to huy all the farming land along Dry creek, the outlet to their mine, which they proceeded to do, the quantity purchased amounting to 16,000 acres. Through a sort of combined system of leveeing and irrigation tbey have succeeded in increasing the value of this land since it came into their possession from two to three hundred per cent., making the investment a very profitable one, and relieving themselves against the threat of further litigation at the same time. Should the adoption of tbis plan or something like it he found expedient, a part of this muddy water could be advantageously used for irrigating these hottom lands, while a much larger portion could in like manner be disposed of on the dry plains aud prairies adjacent thereto.

So, on the other hand, should the final decision of this question he adverse to the farmers, they, by uniting their means, might be ahle to divert much of this water from the bed of the streams where it now flows and employ it in the manner above suggested. Whichever party may in the end he left to deal witb this vexatious and troublesome question, may well bope to receive some aid from the State to help them in disposing of it. The extensive tule lands lying along the lower portions of these rivers would afford ample and desirable receptacles for all this mining debris could it he conducted upon them, and that the question of so disposing of this material will shortly take the shape of a practical engiucering problem may reasonably be expected. Rather than see these gold-producing sources cut off, should such result become imminent, the general government would no doubt feel constrained to use its best efforts towards helping to control this debris and carry it upon the great swamps where it is so much needed. In no aspect of the case need we despair of seeing this trouble successfully grappled with and such disposition made of it as will prevent its working any large interest, whether public or private, a serious detriment.

California State Geological Society.

Wall Rocks of the Bodie Auriferous Lodes.

At a regular meeting of the Society, held March 4th, 1879, Melvillo Attwood, F. G. S., read the following paper "On the Wall Rocks of the Bodie Auriferous Lodes:"

To a friend who was aware that I had devoted a very large portion of my time during the past 12 years to the study of rocks enclosing different metalliferous deposits, I am indebted for a collection of 100 specimens of the wall rocks and vein-stones of the principal lodes in the Bodie district.

I have made as careful an examination of the collection as my time and the means at my disposal would allow, and now beg to submit to you, as briefly as possible, the results; but before doing so I wish to state, with regret, that in consequence of ill health I have not been able to visit the Bodie mines, but from all the information I can obtain—by mill returns, reports of the different Superintendents, and by conversation with experienced mining engineers, who have thoroughly inspected the mines—I have every reason to believe that the lodes of Bodie, so far as developed, exceed in richness and extent those of any other district yet discovered in California. For instance, to the best of my recollection, the richest gold rock ever milled at Grass Valley, in any quantity, was taken out of the Allison Ranch mine in 1856, and treated at the Gold Hill mill, then under my charge. The parcel consisted of 21 tons, and yielded at the rate of $375 to the ton.

Some of the richest and most extensive lodes at Grass Valley (the Gold Hill lode for example) were abandoned at 250 feet; a depth at which the Bodie lodes appear only to begin to develop their richness. To give you some idea of the extent of the Gold Hill lode, the croppings can be traced from near the town of Grass Valley to New York hill. They can be seen passing around the head of Rhode Island ravine, over the summit of Gold Hill, and to the west of the residence of the late William Watt; then by the head of Scadden's flat, under where Joseph Woodworth's cabin stood, on to Massachusetts hill, and then following the contour of that hill on to New York hill, very little short of a mile. Underground workings have been made connecting with one another from the head of Rhode Island ravine to Massachusetts hill, and for a considerable distance on the way to New York hill. The underlie of the lode varies with the slope, or inclination of the surface of the ground, the most productive part of the lode being at a depth of from 60 to 120 feet. The red dirt near the croppings of the lode was worked in the different quartz mills and paid largely in 1853 and 1854.

The mode I adopted for the determination of this collection, was first to cut three or four sections, of different degrees of thickness, from each piece of rock, to be used for microscopic inspection; the thicker sections to show color and structure. The thinner sections were used for examination by polarized light. Besides which I prepared one side of each specimen after my new plan, to be viewed by reflected light, with the aid of a common magnifier; photographs taken from the prepared side or face and magnified three or four diameters will, in most cases, show at a glance the character of the rock. I do not think it necessary to give you a detailed description of the microscopic structure of each specimen, so will only state the general conclusions I have arrived at after a careful study of the collection.

I find them all to be volcanic rocks, belonging mostly to the trachyte group; many of them, as shown by the particles of kaolinized feldspar, having been subjected to a large amount of alteration.

Specimens from the Tioga shaft and tunnel so closely resemble the so-called "trachyte amphibole andesite" of Wolkenburg in the Siebengebirge, that the sections and prepared rocks, when placed beside those from Siebengebirge in my private collection, can hardly be distinguished one from the other.

Rock marked "porphyry," from the Syndicate tunnel, is also identical with some of the other Siebengebirge trachytes. A piece of rock from a crossent in the Belvidere mine has the enamel-like appearance of rhyolite.

The specimen marked "hird's-eye porphyry," from the Belvidere, is a "trachytic diorite," and of much the same character and appearance as that of the Comstock rocks, but has not undergone the same amount of alteration. Some of the feldspar crystals have enclosures or microlites of a pyroxenic mineral.

The prepared rock with the section cut from it and marked "A," was found mixed with the vein-stone at a depth of 1,700 feet in one of the Gold Hill mines (Washoe); and the rock and section marked "B" is from the Belvidere mine, Bodie. Compare them and you will see that they are much of the same character and structure. Years ago the Comstock miners applied the term "bird's-eye porphyry" to *country rock*, found mixed with the vein matter, and which, by solfatara action, or some other cause, had been so altered that it contained 80% of silica, and the particles of feldspar so kaoliuized as to lose all their crystalline form, and take the shape of rounded spots, of a whitish color; hence the name.

The Mount Davidson diorite, was for a long time termed syenite. The black dyke, a dolerite, was called "andesite," and the "trachytic diorite," a rock, the proportion of silicia in which, being too large to be classed with the basic, and too small for the acidic group of igneous rocks forms one of the intermediate links between the two. It went by the name of "porphyry,"—"feldspathic porphyry," "hornblende porphyry." Baron Richtbofen named it "propylite." The Comstock lode was also called a true *fissure* vein, with syenite on one side and a *clay* wall on the other. Rocks sent me from some of the deep workings at the Virginia end of the Comstock, both east and west of the ore bodies, show that whatever the rocks might have been near the surface, or in the upper workings, they have imperceptibly merged into and become rocks of the same basic character as the Mount Davidson diorite.

It is generally admitted by geologists that metalliferous veins or lodes (I prefer the Anglo-Saxon word, lode) are of *aqueous* origin, and that the metalliferous matter occupying *portions* of previously existing fissures, was introduced through such agency; and, thanks to the microscope for its aid in removing all doubts on this subject, as the inspection of vein-matter by it, shows immediately that it possesses certain definite structural characters distinguishing it from the enclosing rock. The arrangement due to successive depositions of minerals on the side of a fissure sometimes gives the vein-matter the appearance of a sedimentary rock.

The *Philosophical Magazine* for December, 1871, published a paper written by John A. Phillips, E. C. S., "On the connection of certain phenomena with the origin of mineral veins," wherein he says: "In the present state of our knowledge we are unable to explain all the various phenomena which we have observed in connection with the origin, composition, structure and mineral constitution of veins; but a careful consideration of ascertained facts would appear to lead to certain general conclusions, forming a sort of skeleton map, of which the details remain to be filled in by the aid of further research.

"First: Metalliferous lodes are more numerous and productive in the vicinity of igneous rocks than elsewhere.

"Secondly: There is abundant evidence of volcanic eruptions having taken place during all periods of geological time.

"Thirdly: Solfatara action and thermal springs are often the latest active evidences of volcanic disturbance.

"Lastly: Crystalline quartz, iron pyrites, sulphide of mercury and various other minerals are at the present time being deposited by solfatara action, in veins possessing many of the characteristics of ordinary lodes."

Again he says: "At the 'Sulphur Bank,' on the shores of Clear Lake, California, is a solfatara some six or seven acres in extent, where a much decomposed volcanic rock is traversed by innumerable fissures, from which steam, together with carbonic and horacic acids, is continually issuing. Sulphur is deposited on the sides of the crevices; and gelatinous silica is found coating chalcedony and opalescent silica in various stages of formation, from the gelatinous state to that of the hardest opal. This indurated silica is sometimes nearly colorless, but is more frequently permeated by cinnabar and iron pyrites, or blackened by a tarry hydrocarbon. Cinnabar is also found in striæ and occasionally in veins, as well as in concretionary masses of considerable size.

"Section of chalcedony and semi-opal from this place, when examined under the microscope are often found to enclose crystals of pyrites together with crystalline cinnabar, although the latter mineral has generally been deposited in an amorphous state. A specimen of chalcedony taken from one of the fissures in the Sulphur Bank, which on being first broken was exteriorly so soft as readily to receive an impression of the nail, had on reaching this country become hardened, and had assumed the ordinary characteristics of that mineral. Thin sections of this specimen show a structure resembling fine-grained fortification agate, and are traversed by numerous fissures filled by opaque oxide of iron. Fig. 2 is intended to show the appearance of a section of this substance magnified 30 diameters. When examined between crossed prisms, brilliant colors are obtained, and the crystalline structure becomes exceedingly distinct."

The two specimens and sections which I have brought for your inspection, are made of the same character as those described by M. Phillips—one marked *C*, is vein-stone from one of the Bodie mines, and the other, marked *D*, from a solfatara in Lake county. Mixed with the vein-stone from the Dudley mine, Bodie, are stains of cinnabar.

To those who feel interested in this subject, I recommend the perusal of Mr. R. Daintree's paper "On Certain Modes of Occurrence of Gold in Australia," published in "Quarterly Journal of the Geological Society," August, 1878.

With regard to the time of introduction of gold into the rocks of California, I think all evidence goes to show that it occurred at two very distinct geological epochs. The wall rocks of the auriferous lodes of Grass Valley, for instance, are for the most part composed of diorites, or diabases-basic plutonic rocks, and the gold met with in those rocks must have been formed during the *first* or earliest age. On the other hand, the closing rocks of the auriferous lodes of the Bodie district, are acidic volcanic rocks, and belong to the trachyte group. Consequently the gold in those lodes must be of a later or secondary age. During the volcanic period the deep placers, or ancient rivers, with the gold of the *first* age mixed with the gravel in these beds, were covered over to a depth of many hundreds of feet by volcanic ash, basalt, trachyte and other mineral volcanic products, their courses were changed, and the ancient Yuba, before the volcanic periods, is now at a much higher level than the present Yuba.

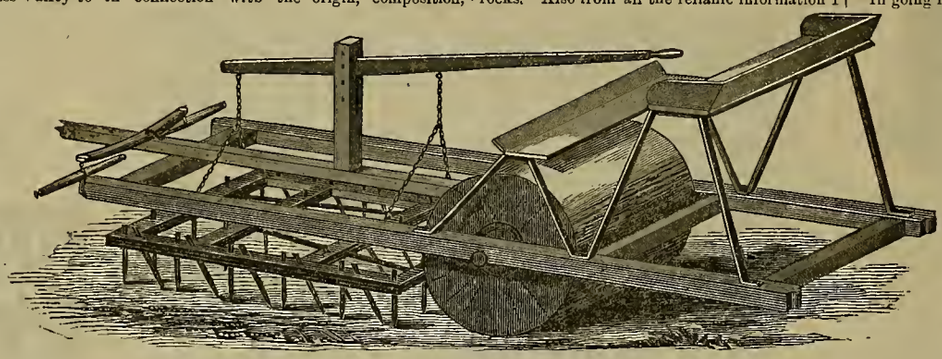
The gold of the Bodie shallow placers and lodes, must have been introduced subsequent to the volcanic period.

Conclusion.

I have briefly stated to you the results of my examination of the collection sent to me, and from it I am of opinion that the Bodie lodes are undoubtedly of aqueous origin, and that the rocks encasing them are all igneous—volcanic rocks. Also from all the reliable information I can obtain, gold has been found in paying quantities at greater depths in those rocks than in the older or plutonic ones. The gold in volcanic rocks is generally adulterated, or higly argentiferous. Mineralized silver is also found in more or less quantities, mixed with the vein-matter.

I have heard from good authority that a large parcel of between 900 and 1,000 tons of vein-stone was taken from the Bodie mine and averaged in gold upwards of $600 to the ton. This would be the richest rock in quantity that I ever remember seeing taken out of any California mine.

I do not hold any shares in any mine either in California or Nevada, neither am I interested directly or indirectly in any of them, and my sole object in addressing you is in hopes that it may be the means of directing attention to the subject of wall rocks, and thereby cause others to work in this comparatively unexplored field. The application of the microscope in these investigations is, however, absolutely necessary, and I am in hopes the day is now past when such remarks as that "mountains should not be looked at through microscopes" will not be listened to by any intelligent person.



NEIL CAMPBELL'S COMBINED HARROW AND ROLLER.

Campbell's Combined Harrow and Roller

We illustrate on this page an improved combined harrow and roller, invented by Neil Campbell, of Ætna, Siskiyou county. The frame work is made large enough for both harrow and roller. The roller is formed of a solid log with bands of iron around it, the spindle being journaled to it in the ordinary way. On the cross bar behind the roller is placed a strip of iron, which acts as a scraper and keeps the roller clean.

The harrow is formed of four cross bars and longitudinal binding pieces. As many lines are drawn across these cross pieces as there are lines of teeth in the harrow. The teeth are then inserted on each alternate line until the harrow is full, and then the remaining lines are filled on each bar alternately, one-half the teeth being placed so as to stand at an angle of 45°, as shown. This method of placing the teeth causes them to stand far apart at the points, although within an inch and a half of each other.

Two iron bars pass through the harrow, to which is secured a chain, the other end of which is hooked to the under side of the pole, thus answering as a draft chain.

Immediately above the harrow and bolted to the pole is a standard or post. Slots are made through this post and a pin passes through them to hold the lever in any desired position.

From this lever extend downwards two chains, one connecting with each end of the harrow, as shown. The driver, from his seat in the rear, by pulling down on the rear end of the lever, raises the front end of the harrow by means of the chain; or can by similar means depress the front end and raise the rear end, as desired. In this way the harrow can always easily be cleaned from rubbish or weeds.

In going from one field to another the harrow can be raised entirely from the ground by putting a small piece of wood, which may be kept always at hand on the seat, under one end of the lever and by raising up, the harrow is suspended from the chains above the ground. A stay chain from the frame to the double-tree takes the strain off the pole in turning. The horses can be hitched ahead or otherwise, four in number or six, according to the size of the machine.

In this way the harrow and roller are combined for cultivating the ground and the harrow so arranged that it is easily cleaned of weeds, and may be lifted off the ground in moving from one field to another. The driver can ride in using this harrow, the seat being placed at the rear end, so as to balance the pole, as shown.

Questions Answered.

In reply to inquiries from "Miner," of Bingham Canyon, Utah, we may say, we know of no *specific* for the prevention or cure of headache caused by inhaling the fumes of giant powder—that is, nothing taken internally will have that effect. Some miners claim that tobacco smoke has a tendency to that end, on the principle, we suppose, that one poison may sometimes be relied upon to counteract the effects of another. Dr. Blatchley of this city has invented and patented a plan which, where practicable, has been found effective for laying and rendering innocuous the fumes of giant powder. By this plan water is introduced into the place where blasting is going on through a pipe or hydrant ending in a closed and finely perforated nozzle, from which the water issues in a fine spray that is said to effect the end desired without fail.

By the manufacturers of giant powder or dynamite it is claimed that this substance will not explode at a temperature of less than 160° Farenheit. Where this occurs at a lower temperature, they attribute it to radiated heat, expressing a doubt about there being any well authenticated cases where this has happened.

There is no machine to be obtained on this coast for grinding small samples of ore, the mortar and pestle being mostly in use here for that purpose; iron discs with a flange about the edge being also used and well-liked by some. A small Blake's crusher, well adapted for use in an assay office, can be obtained in New York.

The Water-Making Snow.—The late storms have deposited a pretty good body of snow on the Sierra Nevada, thereby greatly improving the water supply prospects of the hydraulic mines. These snow falls that occur so late in the season, not becoming much impacted before the warm weather, melt rapidly, and therefore fail to prolong the water season, like those that come earlier in the winter. Still, there being so much of this late snow, it cannot fail to keep the mountain streams replenished pretty well into summer, thereby removing the fear entertained by the miners, that they should be left with a ruinously short water supply the coming spring.

Hope it is True.—Specials from Texas state that several Mexicans who were among the murderers of Judge Howard and Messrs. Atkinson and McBride, at San Elizario, have been arrested and put in jail. The numerous friends of Mr. Atkinson in California would be gratified to have this news confirmed.

Real estate has taken a start forward in New York.

Tempests and Snow Drifts.—The snow storm that commenced on the Sierra Nevada mountains last Saturday night was attended by a perfect hurricane, which whirled the falling particles into heaps that entirely covered many of the buildings and so obstructed the railroad track that it took the relief train, with all their enginery of snow plows, three days and nights to clear it sufficiently for trains to pass.

Business Directory.

WM. BARTLING. HENRY KIMBALL

BARTLING & KIMBALL,

BOOKBINDERS,

Paper Rulers & Blank Book Manufacturers.
505 Clay Street, (southwest corner Sansome),
SAN FRANCISCO.

LEWIS PETERSON. JOHN OLSSON.

PETERSON & OLSSON,

Model Makers, and Manufacturers of Emblematic Signs. Models for the Patent Office, in Wood or Metal, a Specialty.
NO. 328 BUSH STREET,
Bet. Montgomery and Kearny, (up stairs), San Francisco.
All kinds of tin, copper and brass work made to order.

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery of the latest and most improved kind, and are again prepared to fill orders for Rope of any special lengths and sizes. Constantly on hand a large stock of Manila Rope, all sizes: Tarred Manila Rope; Hay Rope; Whale Line, etc. etc
TUBBS & CO.,
611 and 613 Front Street, San Francisco

DEFLECTED HEAT!

Boswell's Combined Heater, Cooker, Baker, Clothes and Fruit Drier.

Combining the advantages of a Stove, Furnace, Oven, Dry House and Kitchen Range. An application of Scientific Principles to the economy of living, of labor, of health and of comfort. A handsome piece of Furniture adapted to the wants of every family. It equally economizes time, labor and fuel, and avoids exposure to heat in cooking as well as in baking. It bakes Bread, Cakes and Pies to any desired tint without turning or watching, or danger of burning. All odors produced in cooking are passed up the flue. Food cooked by deflected heat is improved in flavor, more easily digested, contains more nutriment, will keep fresh longer, and is also much improved in appearance. The stages of the cooking or baking can be seen without stooping or opening the doors of the oven. It will dry and bleach your clothes in from half an hour to one hour and a half, and heat your irons.
Fruit dried in the Boswell will gain from TWENTY to FORTY PER CENT. in WEIGHT, and THIRTY PER CENT. in QUALITY over that dried by any other process. It will successfully dry any kind of Fruit, Grapes, Berries, Meats, Fish, Vegetables, Coffee, Tobacco, Corn and Grain of all kinds.

— ALSO —

Boswell's Commercial Fruit Drier,

Used exclusively for drying and heating purposes ON A LARGE SCALE.

— ALSO —

BOSWELL'S CABINET HEATER,

Of all sizes and capacity for heating Private Residences, Hotels, Halls, School Houses, Churches, Offices, Stores, Railroad Cars, Hospitals, etc.
All of which can be operated successfully by a mere child. It is so simple in its construction, and with one-third the usual amount of fuel (coal or wood), used in any other heating, cooking or drying apparatus.
Every farmer and economical housekeeper should use it. It will pay for itself in the saving of fuel; it will pay in the superior character of its FRUIT DRYING, of its COOKING, ROASTING and BAKING; it will pay in its salubrious and healthful warm air; it will pay the rich and the poor alike.
Address, for Price List and descriptive illustrated circulars,

Boswell Pure Air Heater Co.,

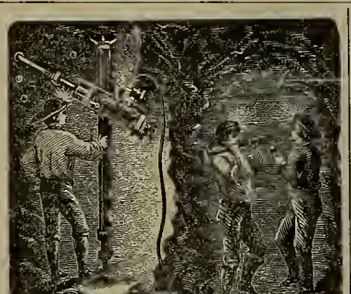
The best Work done on the most reasonable terms on the Coast.

Ingersoll Rock Drills.



In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS, RIX & CO., 18 & 20 Fremont St., San Francisco.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and placer mining in various parts of the Pacific Coast. Over five hundred orders have been filled, and the demand is constantly increasing. A large number of these Plates were sent to Snake River mines, Idaho, last year, and a great many orders are being filled for them this season. Circulars containing full instructions for working these Plates sent with each order. Old Mining Plates bought or taken in exchange for new Silver Plated Plates, and full value allowed. Gold extracted from old Plates at a moderate cost by a new and economical process. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed.

Mining Men and the public generally are cautioned against unprincipled and irresponsible parties traveling through the country, endeavoring to secure orders for very inferior qualities of Silver Plated Mining Plates.

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,

North Bloomfield, Nevada Co., Cal., October 1st, 1878.

HERMAN H. HORST, Prop'r.

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

Barlow J. Smith. M. D.

Consulting Physician,

Professor of Phrenology and Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenological Institute, 635 California Street, above Kearny.

This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervo-vital derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-motopathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermal, Russo-Turkish and Medicated Baths given daily.

Mrs. Dr. Smith as Matron has charge of the female bathing department.

DR. SMITH has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiognomy, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness; whether CONSUMPTIVE, DYSPEPTIC, RHEUMATIC, APOPLECTIC, NEURALGIC, LEUCORRHŒAL, or SEMINAL. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds.

Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Fowler and Wells' charts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph.

Phrenological or Physiognomical examinations without charts, $1.50; with charts, from $2 to $3.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 8 P. M. Sundays from 9 A. M. to 12 M.

BELTING AND LACING.

507 Mechanical Movements.

Every mechanic Should have a copy of Brown's 507 Mechanical Movements, illustrated and described. Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, $1, (post paid.

[Continued from page 165.]

750 level shows more streaks of low grade ore than at any time yet. Crosscutting at that point will soon be in order. The south lateral drift on the same level is also showing improvement.

ALTA.—Good progress is being make in the double winze on the line with the Benton. No change in the north drift 1550 level, which still skirts the ledge and follows the clay.

BELMONT DISTRICT.

BELMONT.—*Courier*, Mar. 1: All parts of the mine are without change during ths past week. Stopes are looking well and yielding an increased amount of pay ore. Ws have advanced south raise—north end of mine—since last report, 27 ft in a well-defined vein of quartz, assaying from $25 to $38 per ton. The ore assays a little more every foot advanced in hight, and will not be long before it will pay for mining and milling. Have also advanced 300 level drift 12 ft in hard blasting ground. Number tons of ore extracted for the week, 15; average assay, $96.

HIGHBRIDGE.—There is no change to note in the upper workings of the mine except in the extreme north stope, the ore is lower grade than formerly though it pays well for extracting and milling. Have advanced the drift on lower level north 17 ft, south, 18 feet. Hereafter shall make bullion shipments oftener on account of the stage not being able to carry at a trip so large an amount as has been previously shipped.

OILA.—There is no change to report in either the east crosscut or winze from it during the past week. In the former we have run 17 ft, and in the drift from the latter 21 ft, with nothing new developed in either. The stopes just started in the south drift are looking remarkably well; much better than was expected. A small force of men as yet have been at work upon it, but the number will be increased as soon as openings are made.

EUREKA DISTRICT.

THE RICHMOND MINE.—*Sentinel*, Mar. 8: This mine ships about 200 tons of ors daily. A large force is employed around the hoisting works, and everything has a lively and business-like appearance. The work progresses satisfactorily under Mr. Rickard's supervision, aided by Messrs. Sam. Longley and William Harris.

PHŒNIX.—The incline shaft is down about 150 ft, and the work is pushed forward rapidly. The giraffe in the incline is a large one, weighing about three tons, and could not work in a better manner. The usual force of men are employed under Pat Rositer as foreman and W. H. Davis as night boss.

JACKSON.—Everything is running smoothly and about 50 tons are shipped to the Metamoras daily, with every indication that the amount will be increased shortly. This amount, with what they buy at the furnace, keeps it running regularly. Mining men claim that at no distant day the Jackson will develop into one of the most valuable properties in the district.

THE K K.—The shaft is down to the 800 level, and they are now cutting out for the station at that level. The water is easily handled, the tank bringing up 800 gallons every four minutes when necessary. Prospecting on the upper levels continues as usual.

THE HAMBURG.—Superintendent Powell, in his weekly report, says the intermediate drift was run 17 ft during the week, and is now within 45 ft of the upraise from the end of the south drift on the 450 level. There is no special change to note in the size or quality of the vein of ore. The east crosscut of the 400 level has been continued 12 ft, making a total of 23 ft, with the face in clay and iron. The 600 level, west crosscut, has been advanced 19 ft, being a total of 169 ft from the main south drift, with face in vein matter. The south drift from the main crosscut has been advanced 18 ft, being a total of 107 ft, with no material change. The winze was sunk 10 ft, making a depth of 69 ft below the 600 level. The hoisting machinery at the mine is in good order and working well.

REESE RIVER DISTRICT.

MANHATTAN ITEMS—*Reveille*, Mar. 8: The ore body in the Curtis shaft, above the 517-west drift still holds good ore. The drift is being push ahead in order to open out a stope. The 560 stope has nearly reached the 517 drift on the top ledge. The bottom ledge though small, carries very rich ore and has been breasted up very little. The 825 stope is being opened along the level and continues to carry very high grade ore; but only a limited number of men can be worked on account of ventilation. Sinking the winze in the North Star shaft, 600 west drift, is making very good progress.

WESTERN NYE.—Grantsville *Sun*, Mar. 8: Specimens from the Ward mine are fairly aglow with ruby silver. There are now on the dump four tons, which will go $1,500 per ton; 16 tons, which will go $800 per ton. The vein so far varies from a few to 24 inches in thickness; depth of incline 700 ft. and perfectly dry, being drained by other mines on Lander hill. The Alexander mine is looking well. The ledge in the south tunnel, it is said, continues in high grade sulphurst ore. It has been penetrated a distance of 24 ft, and no sign of the banging wall yet. This find in the Alexander is daily adding value to the property.

SECRET CANYON DISTRICT.

IRISH AMBASSADOR.—*Sentinel*, Mar. 8: The mine is opened by an inclined shaft 140 ft in depth from the surface. A rich seam of ore continued all the way down for 100 ft. At this point it opens out from two to three ft wide and contains black metal. It looks as if it would assay in the neighborhood of $1,500. The shaft is being sunk through the hardest kind of dolomitic limestone. There are eight or ten tons of ore on the dump.

ARIZONA.

GLOBE.—*Silver Belt*, Feb. 24: A cave in the drift of the Washington is reported; nobody hurt. The vein in the Silver Queen drift, 120 ft deep, is found six ft wide, and is well defined. The quartz looks much better than in the drift 30 ft above. Work has been suspended on the mine, as Mr. Crane is about to leave for California. On his return work will be resumed. The ore worked from the Centennial mine at the Miami mill went very high. A piece of rich ore the other day was taken from the Stonewall Jackson shaft 260 ft down. It was a fine-grained quartz with silver sulphurets all through it. The ors in the Alice shaft has improved. Nodules and spots of rich black sulphurct are occur in the ordinary vein rock. An assay made recently went over $3,000 per ton, the piece of course being selected and freed from waste. Lieurance Bros. & Co. are working on the Mattie West lode, near the McCormick mine. There is a 20-ft shaft on the ledge. Some rich ors has been found in the croppings. Good ore is still being obtained from the Miami lode. The Buckeye shaft is 230 ft deep. The ore will go about $70 per ton. It is not known how large the vein is, but a crosscut will be run for the hanging wall. There has been some excitement at the Richmond basin over the re-location of the McDowell claim, which, it is said, had insufficient work done on it. The claim in question was the northwesterly extension of the Mack Morris mine and is, no doubt, valuable ground.

OTHER NOTES.—*Sentinel*, Mar. 1: Work on the Tiger mine has been prosecuted with vigor. The immense hoisting works are finished and in successful operation. The mill will be running by ths middle of May. A new shaft has been opened; it is now down 70 ft. There are over 500 tons of fine ore on ths dump. The company has spent already $120,000 on the mine and machinery. The ore is rich in sulphurets and free silver, and is very tractable. The Blackburn gold mine has its main shaft down over 90 ft, and sinking is being pushed night and day. Another rich mine has been discovered this week in the Papago country, by Dr. DeCorse and A. Contreras. It is just across the Mexican line. Considerable mining for placer gold has been done this winter by Mexicans, around the Ellen Gowan, Spruce, and Hemlock mines, in Montezuma district, near Castle Dome. These are copper mines, but carry considerable free, coarse gold, which is washed out of their debris.

News in Brief.

NAPA CITY is under water.

GERMANY is free from the cattle plague.

THERE is a glut of silver in Austro-Hungary.

A MOVEMENT is on foot in tbis city for holding a woman's mass meeting in support of the new Constitution.

THE settlers on the Los Bolsas rancho, Santa Barbara county, spent $14,000 in litigation with the land company.

TEXAS expends from $150,000 to $200,000 annually to support a battalion of State troops for the protection of the frontier.

IN the mining debris case, at Wheatland, Judge Keyser has granted a perpetual injunction against the Little York mine.

THE body of policeman Chamberlain, wbo disappeared from Sacramento 10 months ago, bas been found in the Sacramento river.

THE Los Angeles Woolen mill reservoir, containing 100,000,000 gallons, hurst its dam on the 6th inst., flooding the lower portion of the city.

KEENE bas offered $10,000 reward for the detection of tbe person who forged his name to the dispatch in connection with tbe recent wbeat conspiracy.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington. D. C.

FOR THE WEEK ENDING MARCH 4TH, 1879.

IMPROVEMENT IN SYSTEMS OF PUMPING AND COOLING—E. J. Molera and J. C. Cebrian, S. F.

QUARTZ-MILLS—D. H. Anderson, S. F.

MUSIC-LEAF TURNERS—O. H. Goodwin, S. F.

SEWING AND EMBROIDERING MACHINES—L. C. Mumford, S. F.

CORK-EXTRACTORS—L. C. Mumford, S. F.

METHOD AND APPARATUS FOR PHOTOGRAPHING OBJECTS IN MOTION—2 Patents—E. J. Muybridge, S. F.

WAVE-POWERS FOR PROPELLING VESSELS—J. B. Oreene, Elliott, Cal.

INSECTICIDES—J. C. Benton, Santa Barbara, Cal.

BED-BOTTOMS—W. H. Leininger, Salem, Ogn.

AMALGAMATORS—P. Dickson, Spearfish City, Dakota Ter.

SAUCES—Trademark—J. Lusk & Co., Oakland, Cal.

OINTMENTS—Trademark—J. L. Standart, Lemore, Cal.

——The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telgraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

WINDING ATTACHMENT FOR CLOCKS.— S. Serighelli, San Francisco. This invention relates to an improved winding attachment for clocks, and consists in placing at any desired point under the floor at the main entrance of a building the works of a clock, which are so connected with a movable section of the floor that the weight of the persons passing over said floor section will depress it and thus wind up the spring which furnishes power to the clock movement. The dials may he placed at suitable points in different parts of the building, the one movement furnishing power to the various dials hy means of endless cords passing around the main drum, and thence through tubes and over and under small pulleys to the drum bebind the dials, which is mounted on the shaft carrying the hands. Small pulleys are enclosed at the corners, where the line of direction of the pipes through which the operating cords are led is changed. The cord operates without stopping, and any slack is automatically taken up. Measures are also taken to prevent over-winding. This device is a very ingenious one, and is especially adapted for large buildings where there are a number of clocks, as they can all be run by one movement and receive no care. Several of these are running in this city at present.

EXPANSION PULLEY.—S. Serighelli, S. F. This expansion pulley is used by Mr. Serigbelli in connection with his improved clock, but is adapted for all purposes for which pulleys are made, being specially useful for lathes, sewing machines, etc. The pulley is formed in sections, each of which has attached to it a staple or lug, which projects through a slot so as to come through a disk of metal. On the opposite side of this disk are springs corresponding in number to the sections of the pulley, and to each lug or each section is fastened one of the springs. The pulley sections are then eacb one attached to the disk by means of the lugs and springs; but the elongated slots admit of a certain amount of play to the lugs and sections outwardly from the center. The shaft on which the pulley is mounted is threaded and a cone is screwed on to it, so that when the cone is screwed up so as to enter a central slot it pushes the sections apart and increases the diameter of the pulley. This action brings a tension on the springs which hold the sections to the disk, and when the cone is screwed back the springs draw the sections together again and decrease the diameter of the pulley. This expansion pulley is very simple in construction and operation, and is especially useful in small machines for tigbtening belts, etc. Mr. Serighelli's address is 694 McAllister street, S. F.

RODENT EXTERMINATOR.—John C. Benton, Sauta Barbara. This invention relates to that class of compounds used for poisoning squirrels, gophers, rats and other rodents, and that which is new and valuable in it consists in the combination of poisons tbat will be immediately and surely effective, and so combined with other materials as to preserve the properties and powers of the poisons, and render them safe and convenient to handle and use, and, especially, rendering the compound so attractive to said rodents, tbat they will eagerly seek and eat it.

PROPELLING VESSELS.—James B. Green, Elliott, San Joaquin Co. This invention relates to an improved method of propelling vessels hy wave power, and tbe improvements consist in mounting upon timbers or frames projecting over the end of the vessel, a series of frames carrying movable buckets or paddles. These buckets are hinged at their forward ends and the after ends have a certain amount of vertical play. As the vessel rises and falls on the waves, the huckets automatically alter their angles, so that the power of the wave will force the vessel ahead. Means are provided for raising the frames, carrying the buckets out of the water when it is desired to stop their action.

The Mechanics' Institute Fair.

The Managers of the San Francisco Mechanics' Institute have begun preparations for their annual industrial exhibition. The date has been fixed for opening, August 9th, and for closing, September 6th. At the annual meeting held this week, Irving M. Scott, President, made a few remarks preparatory to presenting his report. He stated that during the last quarter the officers of the Institute had been busy attending to the affairs under their charge, and although the library room was inadequate to hold the hooks now in it, they had concluded to postpone contemplated improvements until after the next exhibition. The building was in good condition, and only required a few alterations to make it answer every purpose. He then gave the condition of the various funds of the Institute and other matters of interest, as follows: Library room and building fund, $890.01; pavilion fund, $267.48; sinking fund, $782.34; total on hand March 1st, 1879, $1,939.83. During the year 644 persons have joined the Institute, beiug au average of 53 each month. At present there are 1,711 members, a gain of 61; life members 142, a loss of 6; honorary members 5, a loss of 1; total membership on March 1st, 1,858. During the year 1,886 new volumes have been added to the library—an average of 157 each month; and the circulation for the same time was 65,302 volumes—an average of 5,441 per month.

D. A. McDonald, Vice-President of the Institute, was then introduced, and made a short speech, in which he congratulated tbe members on the prosperity of the Society, and the harmony and good feeling that prevailed at the meeting.

After the returns of the election for Trustees, on the 3d instaut, had been read, Irving M. Scott, Columbus Waterhouse, A. D. Fish, Nathaniel Hunter, A. W. Starbird, James Drury and F. A. Frank, the Board of Trustees elect, took the oath of office, and the meeting adjourned.

New Incorporations.

ORIENT AND OCCIDENT O. & S. M. Co.—Object: To mine in Mexico. Capital, $10,000,000. Directors—L. B. Clark, W. A. Roberts, D. W. Donthitt, F. MacCrellish, R. R. Clark, W. P. Edwards, Jr. and J. S. Jefferies.

GREAT REPUBLIC G. M. Co.—Capital, $10,000,000. Trustees—W. H. Harper, John H. Collins, George W. Smith, Frank Tippets and Charles Jost.

NOONDAY CON. M. Co.—Capital, $10,000,000. Directors—R C. Hooker, George B. Root, William B. Carr, William J. Taylor and O. A. Holden.

PACIFIC COAST OIL Co.—Object: To deal in oils and oil lands. Capital, $1,000,000. Directors—Charles N. Felton, L. D. Fisk, George Loomis, George W. Heges and E. H. Forester.

NEVADA COUNTY CON. PLACER M. Co.—Capital, $12,500,000. Directors—E. Derbec, J. T. Morgan, N. P. Brown, E. M. Preston, E. Hamilton, A. Nivens, Jr. and John Pattison.

OMEGA BLUE GRAVEL M. Co.—Capital, $12,500,000. Directors—E. Derbec, J. T. Morgan, N. P. Brown, E. M. Preston, E. Hamilton, A. Nivens, Jr. and John Pattison.

ALPHA BLUE GRAVEL M. Co.—Capital, $12,500,000. Directors—E. Derbec, J. T. Morgan, N. P. Brown, E. M. Preston, E. Hamilton, A. Nivens, Jr. and John Pattison.

GREAT WASHINGTON BLUE GRAVEL M. Co.—Capital, $12,500,000. Directors—E. Derbec, J. T. Morgan, N. P. Brown, E. M. Preston, E. Hamilton, A. Nivens, Jr. and John Pattison.

IRON CAP M. Co.—Object: To operate in California and Arizona. Capital, $10,000,000. Directors—W. Sherman, O. F. Willey, J. A. Robinson, J. R. Larpham and F. H. Horton.

HARTFORD S. M. Co.—Object: To operate in Inyo county, Cal. Capital. $10,000,000. Directors—P. B. Howard, George S. Burnett, M. F. Dailey, B. W. Mudge and W. R. Carton.

OREEN MOUNTAIN M. Co.—Capital, $1,350,000 Directors—H. C. Bidwell, Ivan Prowwattain, R. E. Brewster, P. H. Knauer and E V. Joice.

MORGAN GRAVEL M. Co.—Capital, $300,000. Directors—R. L. S. Hall, William Sherman, D. A. Bennett, R. M. Anthony and D. W. C. Morgan.

LEFLER M. Co.—Object: To operate in Nevada. Capital, $5,000,000. Directors—William Dunphy, W. H. Sharp, Peter Lefler, J. L. King and J. P. Sargent.

OOLDEN STATE CON. M. Co.—Object: To operate in Amador county, Cal. Capital, $5,000,000. Directors—Charles W. Badger, Wingate P. Sargent, Sidney Sargent, Edward B. Partridge and George W. Bibbsns.

BROOKLYN CON. M. Co.—Object: To operate in Bodie district, Cal. Capital, $10,000,000. Directors—W. K. Leveridge, E. S. Noyes, Thomas Wallace, I. M. Menill and John F. McGeoghegan.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

ANY person receiving this paper after giving an order to stop it, may know that such order has failed to reach us, so that the paper is continued inadvertently, and they are earnestly requested to send written notice direct to us. We aim to stop the paper promptly when it is ordered dis continued.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N.E.COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N E. corner Pine, S. F.

REGISTER YOUR TRADE

MARKS.

The U. S Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

Patents for Mining and Farming Lands.

Having completo arrangements with competent and reliable parties in Washington City, by which we are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of patent business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (with or without assistance by local attorneys), will see at once the great advantage of patronizing au establishment that is thoroughly organized and has its representatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be attended to personally by a member of our firm, and satisfaction will be given in all respects.

Correspondence from persons desirous of securing patents for Lands, Mines, Mill Sites, Canal and Ditch property, promptly attended to.

Applicants for patents for mining and farming land, whose claims have been delayed for any reason, will find it to their advantage to consult with us and in ease of necessity secure the services of our home and Washington branch agency.

DEWEY & CO.,

Solicitors of Patents for Lands, Mines and Inventions, MINING AND SCIENTIFIC PRESS OFFICE, No 202 Sansome St., San Francisco.

SUMMER-FALLOWING LAND FOR SALE OR RENT upon the most reasonable terms—in subdivisions of from 50 to 1,000 acres. Climate healthy. Average rainfall over 20 inches annually. Crops sure. A diversity of semi-tropical and other fruits, corn, vegetables, etc., raised with ease. Address for particulars EDW. FRISBIE, proprietor of Reading Ranch, Anderson, Shasta Co., Cal.

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana-British Columbia, and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

FOR SALE.—4-sided 0-inch Molding Machine. Jackson's Agricultural Machine Works, S. E. corner 6th and Bluxome Sts., San Francisco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Griffith Consolidated Mill and Mining

Company.—Location of principal place of business, San Francisco, California. Location of works, Diamond Springs Mining District, El Dorado County, California. NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 1) levied on the 21st day of January, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the 21st day of January, 1879, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the Company, No. 330 Pine street, Room 48, San Francisco, California, on the 26th day of March, 1870, at the hour of one o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale. G. M. CONDEE, Secretary.

Office, Room 48, No. 330 Pine St., San Francisco, Cal.

Office Wide Awake Prospecting and Min-

ing Company.—No. 232 Sutter Street, San Francisco, Cal., February 1st, 1879. Location of works, Picket-Post, Final County, Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the first day of February, 1879, an assessment (No. 6) of four cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 2, No. 232 Sutter Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fifth day of April, 1879, to pay the delinquent assessment, together with the cost of advertising and the expenses of sale. By order of the Board of Directors. C. HILDEBRANDT, Secretary.

POSTPONEMENT.—The delinquent day of the above named assessment has been postponed until Tuesday, the First day of April, 1879, and the day of sale until Thursday, the First day of May, 1879, at the same hour and place. By order of the Board of Directors.

C. HILDEBRANDT, Secretary.

San Francisco, March 1st, 1879.

The California and Oregon Land Company.

—Location of principal place of business, San Francisco, California. Location of Works, State of Oregon.

Notice is hereby given, that at a meeting of the Board of Directors, held on the First day of March, A. D., 1879, an assessment (No. 2) of Forty Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, Room 6, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 10th day of April, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Saturday, the Tenth day of May, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. R. N. VAN BRUNT, Secretary.

Office, 318 Pine Street, Room 6, San Francisco, California.

CARTRIDGE.

GEN. W. S. ROSECRANS,
President.

Fuse Lighter and Fuse.

COL. SAM'L O. GREGORY,
Secretary.

Safety Cap and Fuse.

Electric Cap.

Safety Powder, Caps, Electric Caps, and Fuse Lighters.

Under a series of U. S. Patents, after long and carefully conducted experiments and thousands of tests, this Company is prepared to manufacture and supply, for Mining and Engineering Works, the above named articles at prices and on terms as favorable as articles of similar grades are now supplied in this market. Our Powders contain no Nitro-glycerine, no Nitroline, no Gun Cotton, no Fulminates, and are free from the unavoidable dangers in manufacturing transporting, handling and using of all high grade explosives which contain those elements.

Cold does not affect them. They cause no headaches or other inconveniences in handling, and the smoke from their explosion contains no poisoniug or sickening vapors.

Their blasting force, with slight tamping, at least equals that of any Powders now used, but they admit and require strong tamping to bring out their immense and peculiar lifting power which follows their detonating work. They should be fired, therefore, by our

Safety Cap,

Which allows tamping without danger. They can be fired by any caps now employed in blasting, but the use of these is always dangerous with any Powder, and the loss of the throwing power resulting from lack of tamping renders it with our Powders douhly objectionable.

Our SAFETY CAPS have twice or thrice the force of triple Giant Caps. When set on fire they do not explode, but merely burn off, and are perfectly safe in transporting and in tamping.

In round tin boxes, 50 cents.

The Safety Fuse Lighter,

Cheap, handy and sure to light the Fuse upon the end of which it is fastened, only needs a trial to be appreciated by every miner who is up to "snuffs." 25 Cents per box; sent by mail.

Safety Fuse,

Equal to the best in the market, will be supplied at the lowest market prices.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature, thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

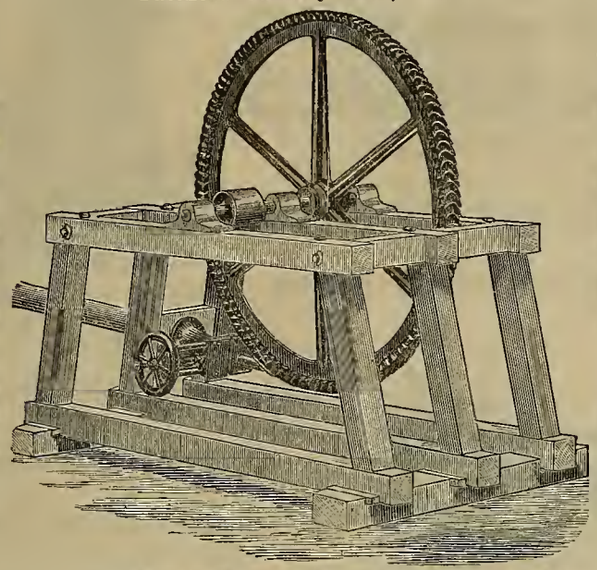
Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

Knight's Water Wheel,

Patented January 12th, 1875.

This Wheel possesses more power for a given percentage of Water than any yet offered to the public. They are in practical use in many Mills and Hoisting Works, and never fail to give entire satisfaction, which facts speak fully for their efficiency, and render further comment unnecessary.



This Wheel possesses more power for a given percentage of Water than any yet offered to the public. They are in practical use in many Mills and Hoisting Works, and never fail to give entire satisfaction, which facts speak fully for their efficiency, and render further comment unnecessary.

The KNIGHT WHEEL is used in the following named Mills and Hoisting Works, to which the Public are referred:

1–Eight-foot wheel, running Oneida Co.'s Mill, Amador county, Cal.; 60 stamps. Rob't Robinson, Supt.
1–Eight-foot wheel, running Con. Amador Mining Co.'s Mill, Amador county, Cal.; 40 stamps and two Hepburn pans. David Davis, Supt.
1–Eight-foot wheel, running Lincoln Gold Mining Co.'s Mill, Amador County, Cal.; 40 stamps.
1–Eight-foot wheel running pump at same company's mine. S. D. R. Stewart, Supt.
1–Eight-foot wheel, running Keystone Con. Mining Co.'s Mill, Amador county, Cal.; 40 stamps.
2–Four and one-half foot wheels, used in hoisting by reversible water power at same company's mine. O. C. Hewitt, Supt.
1–Four and one-half foot wheel, running Original Co.'s Mill, Amador County, Cal.; 40 stamps, one pan, one rock-breaker. J. R. Johns, Supt.
1–Four-foot wheel, running Gover Mining Co.'s new mill, Amador county, Cal.; 20 stamps.
1–Eight-foot wheel, running same company's old mill; 10 stamps. John Palmer, Supt.
1–Six-foot wheel, running Talisman Mining Co.'s Mill, Amador county, Cal.; 10 stamps.
1–Eight-foot wheel, hoisting and driving pump at same company's mine. John Tregloan, Supt.

Iron and Steel Wire Rope,

Flat and Round, for Mining, Shipping, Hoisting and General Purposes.

Having the most complete and extensive Wire Rope Works in the United States, I am prepared to manufacture Wire Rope and Cables of any length or size at short notice, and guarantee the quality and workmanship equal to any made at home or abroad.

Iron, Steel and Galvanized Wire
Of all Sizes on hand or made to order.

Barbed Fence Wire.

Sole Proprietor of
Hallidie's Endless Ropeway,
For the Transportation of Ores, Etc.

JOHN A. CHURCH,

MINING ENGINEER,

COLUMBUS, OHIO.

Paul's Dry Amalgamating BARREL PROCESS.

This is the most perfect of all systems for amalgamating the precious metals—more especially gold, for which it is absolutely perfect, the per cent. of metal obtainable being only governed by the fineness of reduction of ore. It will gather the flour gold with the same readiness as the coarse. The machinery and operation is simple and practical—not requiring skilled labor. Its efficiency is verified by mills in practical operation. I will contract for mills of 10, 20, or 50-ton capacity per 24 hours. Pamphlets, explaining the process more fully, forwarded on receipt of address. For further particulars apply to

ALMARIN B. PAUL,
Room 20, Safe Deposit Building, San Francisco.

MINING AND SCIENTIFIC PRESS.

Quicksilver Combination.

The principal quicksilver producers in California havo about consummated an arrangement whereby the output of that metal will, for a period at least, suffer some restriction; an object that a portion of these companies havo been seeking to effect for several years past, that is to say ever since it became evident that an unlimited production, if allowed to go on, must preclude any of them from realizing a living profit.

But while the most of these companies were willing and even anxious to enter into a combination for this purpose, a few of them held aloof, not quite satisfied with the minor details, or hoping for such early improvement in prices as would obviate the necessity for such action. Disappointed in this, even these companies have at last, it seems, given their adherence to the plan proposed for guarding against the continuance of this ruinous overproduction. We are not advised as to the exact manner in which this is to be accomplished, further than that enough curtailment will be made to reduce production to the requirements of the market. Whether each of the companies now in the field will make a pro ratio abatement of their yield, or whether a few will retire altogether, sharing the profits to arise from an advancement of prices, while the remainder go on turning out their full complement of metal, as before, we are not informed.

It will be observed that this is not a combination entered into to force up prices directly, but to prevent, in the first place, their further decline, and ultimately bring about such advance as will make the business fairly remunerative. For the past two years the best conditioned of these companies have made but little money, the majority of them having been going behind at a rate that has compelled quite a number, after heavy expenditures for outfit, etc., to suspend operations, some of those that have kept on having done so merely in the hope that affairs would soon take a favorable turn. A monopoly of quicksilver or even extreme high prices, can, in no event, be brought about on this coast. We have a multitude of small mines that, while they cannot be worked with profit so long as prices remain greatly depressed, will be started up immediately should the latter undergo any marked advance, some of these mines being already opened and furnished with reduction works.

In adopting the policy proposed, these companies are not without precedents, the manufacturers and producers of certain articles elsewhere having in many instances found it expedient to pursue a similar line of action. Quite recently a course like this was forced upon the manufacturers of borax on this coast, the several companies engaged in the business having, through competition stripped it of all profits. Having, through a mutual arrangement, slightly lessened the production, the prices have so advanced as to leave a narrow margin for profits, where before there were none. Borax, however, is an article of large use and varied application in the useful arts, insuring for it under low prices an increased consumption, which is not the case with quicksilver. For this there may be said to be but a single use, wherefore about the same quantity will be consumed whether the price be high or low. With most commodities the maker or producer finds in the increased demand resulting from low prices some compensation for the latter; but not so the producer of quicksilver, wherefore, when prices drop below a remunerative figure he must devise some method for bringing about an improvement, give up the business or continue it at a loss. An advance in the price of this commodity of a few cents a pound, while it would not lead to any appreciable curtailment of gold and silver production, nor much oppress any class of consumers, would very often suffice to cover the narrow margin that with the producers of this metal divides living profits from dead loss.

Combination Lathes.

The lathe illustrated on this page has been made especially to meet a want felt by many for a really good and substantially made foot-lathe at a reasonable price. The bed, head and tail stocks are of iron, and the spindles of steel. A conical bearing is made for the head stock, so that the wear can easily be taken up. Material eighteen inches long and eight inches in diameter, can be turned in this lathe. The pieces that accompany it without extra charge are two T-rests, two plain centers, one open center for wood turning, and one face plate. The bench is made of iron, with a walnut top and drawer for holding tools. Like the lathe, it is well made in all its parts, and is strong, neat and solid.

Fig. 2 shows a circular sawing attachment, for this lathe is intended for those who desire a good, practical machine, and will be found very effective. The table is of iron, planed true, and can be adjusted as to hight. It has a guide running in a groove at right angles with the saw, and a slide operated in a similar groove parallel to the saw. The slide can also be adjusted to different angles. One each four-inch slitting and cutting-off saws accompany this attachment.

Fig. 3 is a scroll sawing attachment, which, like that for circular saws, is a good and thoroughly practical machine, sawing wood at least one and a half inches thick. It is moved by a pitman connecting it with the face-plate by means of a small stud. The bolt of the T-rest holder is used for fastening this attachment to the lathe, and when not in use it can be thrown back behind the shears without entirely removing from the lathe, unless so desired. The depth between the saw and back, or upright, is sixteen inches.

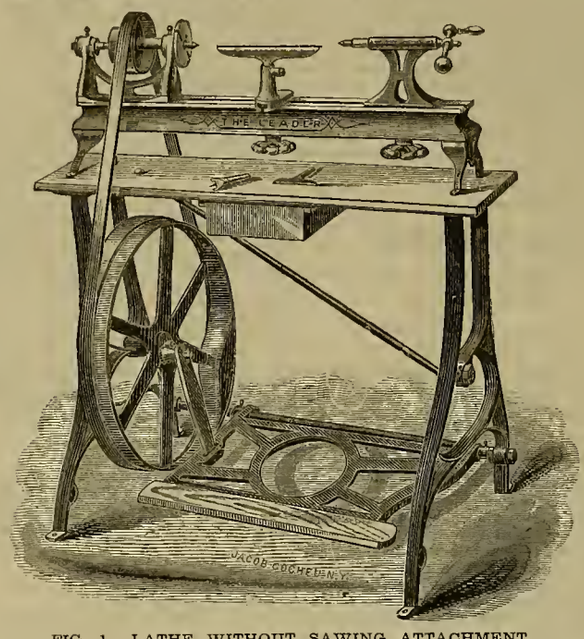

FIG. 1. LATHE WITHOUT SAWING ATTACHMENT.

These machines are sold by Dunham, Carrigan & Co., of this city. The price of the lathe without saw attachments is $45; lathe with scroll saw attachment is $55; and with both scroll and circular saws is $70.

CRYOLITE.—A peculiar specimen of quartz recently sent up from San Diego, and having the appearance of cryolite, was presented to the Academy of Science at the last meeting, under the supposition that it was cryolite. A more careful examination, however, by Mr. Gibbes, the curator of mineralogy, showed that the specimen was only quartz. Cryolite has only, so far, been found in Greenland, and its discovery elsewhere was looked upon as a matter of great interest, as the article is valuable in a commercial point of view. It was a mistake, however, to call the substance referred to, cryolite.

THE Moffett register has proved a failure.

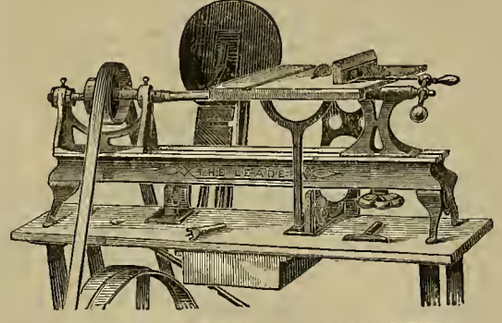

FIG. 2. CIRCULAR SAWING ATTACHMENT.

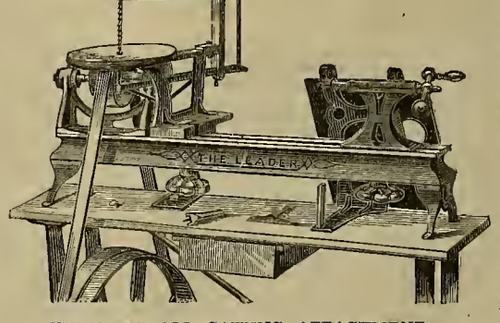

FIG. 3. SCROLL SAWING ATTACHMENT.

The Proposed Free Library.

One year ago the Legislature of California passed a bill establishing a public library in the city of San Francisco, and named the following citizens who were to be charged with the duty of carrying out its provisions: Geo. H. Rodgers, President; A. S. Hallidie, J. S. Hager, Andrew J. Moulder, Richard Tobin, John H. Wise, Henry George, Chas. Terrill, Irving M. Scott, Louis Sloss and E. D. Sawyer. The gentlemen thus commissioned have been actually at work, and during the past six months have made energetic efforts towards its immediate and practical inauguration. Four committees—on finance, books and donations, rules and government, and buildings and rooms,—were then chosen among themselves by the trustees to co-operate in the work of organization. A conference committee, consisting of Mr. George H. Rodgers, the President of Board as chairman, and the various chairmen of the above-mentioned committees, was also appointed to confer with public parties generally, and a corresponding committee from the Board of Supervisors in particular, and to settle and define the details of the work coming under their jurisdiction. The result is that it is expected to open the library to the public on the 15th of May, or the 1st of June at the latest. The committee have all along been hampered by a lack of funds. Eight months ago the Board of Supervisors, in compliance with the law, set aside $2,000 a month as a sufficient fund for the purpose. The comparative smallness of this sum has caused the delay in carrying out the plans, for the Trustees judiciously thought it best to postpone the inauguration until sufficient funds had been accumulated to enable them to make a real start and to purchase a sufficient number of books to form the nucleus of a creditable public library. No money has as yet been spent, but the immediate purchase of from 12,000 to 15,000 volumes has been decided on, most of which have been already selected. This will cover an assortment of all classes of standard works, none of which for the present will be duplicates. This fact, together with the limited number of books necessitated by the scarcity of funds, compels the opening of the library simply as a reading room and place of reference. No circulation can be thought of with but 15,000 volumes on the shelves, but as soon as enough books can be purchased the public will be allowed the priviliges of drawing them out. The whole aim of the Trustees so far, has been economy, and as few expenditures have been indulged in as possible. The working officers will consist of a librarian, assistant librarian, janitor and boy. These positions have been filled or will be soon. The Trustees have secured as librarian, Mr. Albert Hart, ex-State Librarian and ex-Secretary to Gov. Booth, a gentleman whose experience and cultivation in every way fit him for the position.

The choice of a room now rests solely with the Supervisors. Pacific Hall will probably be taken, as it is almost the only place at present available. This is 50x135 and is thought large enough to answer both as library and reading room, similar to the plan adopted by the Cooper Institute. The check system of that association will also probably be adopted, by which a person on entering the library, will receive a check, which he will be obliged to present to the librarian in order to obtain a book from the the shelves. When the borrower of the book returns it to the librarian he receives his check, which he is obliged to show at the door upon leaving the library.

A SLIGHT shock of earthquake was felt in Carson City, Nev., a little after 11 o'clock Tuesday night. The vibration seemed to be east and west.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Nevada's Wealth.

New Boston District, Esmeralda County.

EDITORS PRESS:—It may not fail to interest some of your many readers to learn through the columns of your valuahls paper, of some of the interestiug and important sources of wealth that are scattered among the mountaius of the State of Nevada.

As the State is so closely allied to us in her commercial relations, every interest that increases her wealth hut adds to our coffers, through the merchants aud miners who find their way to San Francisco to replenish their stocks, many of the large mining properties that have been opened up in the last few years, bids fair to rival some of ths most productive of the Stats. I allude to the mine and mill at New Boston, Esmeralda couuty. There are connected with this minc no less than 14 ledges, many of which are very extensive and very rich. Some of the veins ars 16 to 18 feet wide, and are pay ore the width of ledge—making an average of $100 per ton; while ths amount of ore exposed to sight by the prospect work done, is simply fabulous, and will keep a mill running for years. No where in the State did I see such a rich and extensive body of ore.

They havs 13 stamps, a large sized Davis pulverizer and a White & Howell furnace of 50 tons capacity. The ore is rebellious, containing about 25% of copper, but yielded above $50 per ton without roasting. It was expected the furnace would he running in a short time after I was there, and ere this, I presume they are taking out from $2,000 to $3,000 per day, as it was expected the ore, when roasted, would pan out $100 per ton and over of gold and silver, the silver predominating in value.

If this mine was situated a little nearer civilization, it would soon become one of the most promiuent in the State.

The location of the ledges are so highly elevated above the mill that hoisting works are not needed, nor are they troubled with water in the mines, for at the lowest depths of the shafts I found them as dry as a toper at half past 5 A. M. The ledges are true fissure veins with perfect walls, the direction nearly north and south with a dip to the west of about 85 degrees. The work on these ledges was commenced several years ago by the present owner, Mr. A. J. Rhodes, who continued to prospect each one of the ledges, until he became satisfied that they were permanent, he then proceeded to erect his present mill and bring the water from an adjoining mountain some five miles away.

The long distance to transport freight by wagons and the scarcity of lumber, makes mining in Nevada more expensive than in our State, bnt the quantity of ore and its high grade with a careful selection of a ledge, thoroughly prospected, warrants the outlay, and will amply repay the investment.

If the capital invested in fancy stocks, where there is not even a prospect for a ledge, could be diverted into some of these legitimate mining camps, that are sure to pay the investment a hundred fold, what a change would be brought about in our commercial circles, and the disappointments of broken fortunes changed to happy smiles, and the enchanting scenes that follow in the bright pathway of domestic happiness—for prosperity always brings happiness; first to the individuals, then to the community in which the individual resides.

But—excuse my moralizing—I intended to give you facts pertaining to the wealth of Nevada.

The Great Salt Marsh.

After leaving the New Boston camp, I was invited to inspect the great salt marsh, as it is known in that country, and here I met with an anomaly in nature—the extent and numher of the salt springs covering as they do the enormous area of 4,160 acres—the springs, each one of which is separate from the other, numhers over 2,000, and each spring is capahle of yielding one ton of salt per day, the crystallization occurring without any artificial aid whatever. The salt water rises through a perpendicular column of crystallized salt, which neither increases nor diminishes appareutly from the friction of the water, hut as soon as the water reaches the surface, the crystals begin to form, and the salt is gathered hy the attendant with a long handled shovel, who makes his rounds, in piling up the white pearly crystals, in little heaps on the edge of the surrouuding elevatiou.

Not many of the springs are utilizcd, as the owuers cannot fiod sale for so large a product, and it heing 120 miles to railroad, the sale is confined to the local demands.

The salt is the purest in the country, an analysis by a friend of mine, gave the following results:

Chloride of sodium....Na Cl	.95
Free soda.....Na	.03
Biborate soda.....Na Bo 2	.02
Total	1.00

With railroad facilities to hring this salt into market, we could be supplied with the purest articlc over produced at a comparative low price, as I was told it could be gathered and dried and sacked for $4 per ton, including the cost of hags. A railroad is projected, with every probability of its being built, that will leave the Central Pacific at Wadsworth and pass within a few miles of this famous group of salt springs, which alone would furnish sufficient freight to pay a handsome dividcnd on the cost of construction.

Borax.

In addition to the salt springs in this wonderful basin, there are several large hihorate of soda springs that are constantly producing borax. The owner, who accompanied me, took a shovel and excavated a hole in the vicinity of one of these springs, and for two feet down was a solid mass of horax crystals, which had only to be gathered and washed to remove the adhering dirt and it was ready for market. Here were thousands of tons of this valuable product which could be laid down in your city at a few cents per pound if railroad communication was established at or uear this locality; and certainly the supply seems to be inexhanstible, as it is constantly forming. Some two miles away from these horax springs, aud on the opposits side of the salt springs, we were shown an immense deposit of bihorats of lime; the purest I ever saw, samples of which I brought with me, and also send them to you. This deposit is most remarkable, from the fact that its formation is continuous. It would seem that the vapors of boron find their way up through the earth, and, coming in contact with water containing lime, abstract the lime and thus form this wonderful dsposit. The formation is found in small balls resembling cotton in appearance, and upon examination are found to contain beautiful white, pearly crystals of a lamiuar structure, with a soft, silky feeling; insoluble in water.

The sources from whence coms this factor of wealth to the State is hidden within the deep arcana of nature, and is without question one of ths great curiosities of nature's lahoratory. The elevation is over 3,000 feet above the sea, yet it is surrounded by mountain ranges, from whose lofty hights millions of bullion can be taken with proper machinery and a judicious expenditure of money. But no where in the State is there such a concentration of natural wealth as comes rising up in a perpetual stream in this famous salt mash of Esmeralda county; owned by A. J. Rhodes, of Bellville. JNO.

THE ENGINEER.

Cheap Railways.

[Written for ths PRESS by R. GRIMSHAW.]

There is now being agitated in France, the question of cheap public railways; and it is probable that the new law will authorize the establishment of railways on the public roads and streets, subject to the authority of the General Councils as regards construction and maintenance, grades, curves, gauge, etc., the concessions revocable by the "Conseil d'Etat;" speed limited to 20 kilometers per hour, and the whistle replaced by bell or trumpet; no night service; as few trains as possible, say three per day; mixed freight and passenger traffic. As the lines will not be more than 30 kilometers each in length, hut one man will be needed for both "engineer" and "conductor." The speed of 30 kilometers can he reduced near to towns and crossings, etc.,—being averaged by a maximum of 25 kilometers. The charge proposed per traveler is seven centimes per kilometer; and for merchandise, 13 centimes per ton per kilometer. Supposing that the freight and passenger receipts are equal, we will have, say—

Kilometer receipts per year	2,000 francs.
" " " day	5.48 "
" " " train, counting six trains per day	0.90 "

Kilometer units per train:

Passengers $\frac{0.45}{0.07}$ = 6.420 travelers

Freight $\frac{0.45}{0.13}$ = 3.461 tons

This is reckoning, then, on an average of 6.42 travelers and 3.471 tons of freight per train to produce 2,000 francs per kilometer per year.

	Tons.
The proposed train is to have a mixed car (containing two tons of baggage or freight, and six passengers) weighing empty	1.200
Passenger car, 14 places, weighing empty	1.200
Freight car holding 3.6 tons " "	1.200
Weight of 6.42 passenger @ 70 kilos each	.449
Freight	3.461
One empty car weighing	1.000
Total	8.510

The maximum regnlar grade of roads and streets is 5 iu 100, although 6 and 7 are sometimes found. Counting a meau train load of 8½ tons, we shall see that a tank locomotive with three pairs coupled, and weighing nine tons—that is, three tons per axle, can easily draw such a load up a grade of 7 in 100. So the grade will be no trouble. Now about thc curves. We do not wish to go too far iuto the battle of the gauges. There is no question now but that narrow gauges are the cheapest and best paying; the only trouble is about the changing freight from one gauge to another. Still where we are only allowing for a freightage of 2,000 to 2,500 francs per kilometer a year, a wide or "standard" gauge is out of the question; and it becomes necessary to choose the narrow with a rolling stock of 30,000 francs per kilometer—a reasonahle figure.

One of the chief advantages of the narrow gauge is the permissibility of short curves. Of course, with rigid wheels the nearer the wheels the shorter the curve they will turn on and the less resistancs from curves.

Just what proportion to lay down hetween the gauge-width and the minimum curve-radius depends upon many things—such as conicity of the tires, end-play of axles, "play" of ths rails themselves, etc. But the many narrow-gauge railways made and run up to to-day prove:

1. That curves of 80 or 90 meters radius for the meter gauge, and of 40 to 50 meters radius for the three-quarter meter gauge, are as practicable for running as those of 250 to 300 meters for the "standard" gauge.

2. That hy slowing up it is possible to round curves of only 15 to 20 meters radius.

There being light traffic there can he heavy grades. We shall now look at the question of not only whether the rails can follow the grades and curves of ordinary roads, but whether they can be laid thereon *without necessitating widening*. This is a very important question. The three-quarter meter gauge might be laid on one side of most roads, on a raised embankment, leaving sufficient space at the side and yet prevsnting ordinary vehicles from getting into danger. On roads of six meters width the three-quarter metsr gange is the widest that can be thus laid. On very narrow roads it would be necessary to have ths rails at the road level and the track stone ballastcd—and if necessary counter rails could he used so as to permit the track being used by ordinary vehicles.

Iu towns, the track should be in the middle of the road whenever this would leave enough room at each side for a wagon track. If at the side, on account of narrow width it might hinder cars or wagons from standing iu front of stores, etc., especially along a river bank—a very serious iuconvenience. But for rural roads this makes but little difference, as the road need be free but six times a day for a few minutes at a time.

The three-quarter meter gauge permits the use of cars only 1½ to 1¾ meters wide from out to out—far within the maximum permissible carriage width on ordinary roads; the train having the advantage over the wagons, of less width, more docile motors and invariahle track or course. The locomotive does not balk, and can be more quickly stopped than a horse.

There is in Wales a railway of 60 centimeters gauge—that of Festiuiog; in Germany tbere are two of three-quarter meters: that of Broelthal near Cologne, and that from Ocholt to Westersted, near Oldenburg*—both carrying passengers and freight.

The economy in rails is considerable over the standard gauge, a rail weighing 12 kilos per meter sufficing instead of one of 35 to 37 kilos, on account of the maximum weight per axle being but 3¾ tous instead of 12 to 13 tons.

If we suppose the rail supported on two ties, we get its resistance from the formula:

$$R = 0.148 \frac{VPa}{I}$$

In which P is the rolling load on one whcel; a, the distance between the ties; V, the distance from the neutral axis of the most distant fiber, and I, the moment of inertia of the rail section referred to its neutral axis. For the type adopted—

$V = 0.03536.$
$I = 0\,000{,}000{,}887$
$a = 0.68$

The maximum weight of locomotivcs being, say, three tons per axle, we have P = 1,500 kilog. These elements give us R = 6.01 kilog. per square millimeter, quite a safe figure, as the 35 kilog. iron rail of the Vignole de l'Est road carries 8.16 kilog. per square mm., and the 36 kilog. iron rail of the Orleans line bears 8.50 kilog. per square mm.

As regards the power of the locomotive, in the ordinary system the motive force is brought to bear on the resistance of the train by means of adhesion. The resistance increases rapidly with the grade, and, while we can increase the motive force by diminishing the speed, we cannot so increase the adhesion. Hence the systems of artificial adhesion, such as the central rail gripped by horizontal wheels, used on the Mt. Cenis road, and the rack and pinion employed at the Rigi. These are, however, too expensive and otherwise unsuitable for our proposed roads.

We have then to haul a train of 8½ tons on grades of 7 in 100 and short curves. The tank locomotive will do this best as economizing dead weight and increasing adhesion. The engine should have all wheels coupled. The number of axles should be large enough to case the rails, and they should yet he close enough together to give curving capacity. The heating surface should be qnite large, the wheels of small diameter, to lower the center of gravity, round curves easily, augmcnt the piston speed, and the numher of "exhausts" which quicken combustion.

Such dimensions as these would answer:

Weight of tank locomotive, 3 pairs coupled	9 tons
Wheel base	1.50 m.
Boiler pressure	10 atm.
Heating surface, fire-box	2.30 sq. m.
" " tubes	18.9 sq. m.
Diameter of coupled wheels	0.60 m.
" cylinders	0.22 m.
Piston stroke	0.30 m.

This locomotive, hauling three tons on each axle, and wheel base of 1½ meters, conld run on 12 kilog. rails and rouud 15 meter curves. We shall see if it could mount grades of 7 in 100:

Supposing Q thc weight of the train and P the weight of the engine (in tons), the resistance would be—

$$(Q + P)(r + i);$$

r being the resistance to traction per ton on a level, and i the resistance due to gravity, in grades.†

Theory and experience show that i = as many kilograms per ton as there are thousandths of inclination.

The horizontal resistance r increases with the speed, the sharpness of the curves and ths length of ths trains. On steep grades, ths speed would be reduced and in our case ths train length short. We may consider $r = 6$ k. If then Q = 8½ tons, P = 9 tons, $r = 6$ kilog., $i = 70$ k., the resistance in the maximum grade will be—

$$(8\tfrac{1}{2}\text{ t} + 9\text{t}\,(6\text{ k} + 70\text{ k}) = 1{,}330\text{ k}.$$

The adhesion is expressed by

$$\text{f } 1{,}000\text{ P};$$

P being the weight of locomotive iu tons on ths driving wheels; f a co-efficient depeuding on the contacting surfaces, and varying from one-quarter to one-tenth, according to the weather. It is greatest for rails that are very dry or very wet, and weakest for greasy or damp rails. Ws may say one-sixth to one-seventh, and calculate with one-sixth on the maximum grade.

It will run easier on the level and always bs kept up to this on the grades by the use of sand or water. Supposing the water and coal to bs partly used, so that the adhesion is dependent on only 8½ tons weight, we shall have f 1,000 P = 1,416 kilog., while we have a resistance of only 1,330 kilog.

As regards the hauling force, this depends on the heating surface. For slow speed locomotives, each square meter of actual heating surfacs should produce 7 horse-power; the actual heating surface being say ⅓ the tubs surface. Our locomotive should theu have a hauling powcr of—

$$7\left\{2.3 + \frac{18.9}{3}\right\} = 60\text{ H. P., or } 4{,}515$$

kilogrammeters, which may be devided into a work of traction F, at a speed V; that is FV = 4,515 kilogrammeters.

The work of traction at the circumference of the drivers, is—

$$F = \frac{m\,p\,d^2 l}{D} \quad \text{in which}$$

P = pressure per square meter on the boiler; m, a coefficient varying with the cut-off; wire-drawiug, ——; d, the diametcr of cylinder; l, the stroke of piston; D, the diameter of drivers (all in meters). F is at a maximum when m is greatest; that is, using full steam without cut-off; in this case m is taken as 0.65.

If we substitute

$d = 0.22$
$l = 0.30$
$D = 0.60$
$P = (10 - 1)\ 10.333\text{ k} = 92\,997\text{ k},$

we shall have for maximum of F,

F = 1,463 kilog.,

which is all right when the adherence is 1,416 and tbe resistance 1,330 kilos.

When the work of traction is greatcst, the speed is least, and has for value

$$V = \frac{4{,}515\text{ kgm}}{1{,}463\text{ k}} = 3.08\text{ m}$$

or 11 kilometers per hour.

Thus our locomotive on grades of 7 in 100, will not develop its maximum traction effect beyond 11 kilos per hour.

It is interesting to note the effect of steep grades on the useful effect of locomotives. We have—

$$(Q + P)(r + i) = \text{f } 1{,}000\text{ P; whence}$$

$$Q = \left\{\frac{\text{f } 1{,}000}{r + i} - 1\right\} P$$

Making f = ⅛, then

r = 6 K

Giving successive values to i, we have the following table:

Grade per 1,000 (i)	Resistance per ton in Kilogrammes. ($r+i$)	Number of times its own weight a locomotive can haul. $\left\{\frac{f1{,}000}{(r+i)} - 1\right\}$	REMARKS.
30	36	3.611	
35	41	3.049	Appenzel R. R.—St. Germain R. R.
40	46	2.609	Lausaune to Echullens.
45	51	2.255	Enghien to Montmorency.
50	56	1.964	Waedenswell to Einsilden.
55	61	1.721	
60	66	1.515	
65	71	1.366	
70	76	1.184	Utliberg R. R.
75	81	1.05	Tavaux-Ponsericourt

The ahove tahle shows very clearly the economy in easy grades, and we believe that the foregoing figures will he found valuahle not only for demonstrating the advantage of the narrow-gauge, hut for calculating the elements of any desired gauge, grade or curve.

† The friction of the working parts is not counted.

* The rails weigh 12 kilog. per meter.

WIRE BELTS.—A German firm is manufacturing, woveu steel wire belting, of a peculiar make, as described below, which they claim to transmit power well, to operate without lengthening, and to run smoothly because there is no overlapping at any place. The spirals of wire are woven across the helting, so that three, four or more spirals form one link. The space betwcen two links is besides, filled up with a cross-piece, so that the closely woven netting of spiral wire forms a baud of great strength and flexihility. It is faced and lined with rubber or leather.

MECHANICAL PROGRESS.

Welding of Metals at Low Temperatures.

Some tims ago, iu order to estimato ths amount of hydrocyanic scid in a solution, Mr. Charles A. Fawcett, of Glasgow, Scotland, procipitated it with silver nitrate. After having filtered aud washed tho precipitate, he reduced it to tho metallic state by heating to the required temperature. Just as ho was about to allow it to cool ho noticed a small piece of dirt among tho reduced silver. Iu order to separate thsm he took a thin platinum wire and pushed the silver to one side, but on attempting to take the wire away the silver remained in contact with it. As he thought this curious, he tried the following experiment: Ils took a piecs of silver foil, about one centimeter square, placed it in an inverted porcelain crucible lid, and heated it to about 500° C.; then he brought into contact with it the extremity of a thin platinum wire, and to Iris astouishment tho wire raised the silver from tho lid, and it remained in contact when cold.

Tho silver being so much below its melting point, its behavior puzzled him, so he wrote to Sir W. Thomson for an explanation. On witnessing the experiment, Sir William prouounced it a remarkablo case of "cohesion," the two metals, in fact, "welding," although the temperature was far below the melting point of silver. Mr. Fawcett says that tho experiment can be performed successfully at lower temperatures than 500° C., if smaller piecos of foil are taken; and that other metals, for instance, copper and aluminum, cohere to silver in the same manner as platinum, but less strikingly.—*Scientific American.*

Motive Power from the Condensation of Steam.—The water from a lodge is, accordiug to the invention of Mr. Robert Wortley, of Oldham, England, conveyed by pipes into a well ahout 20 feet below the level of the lodge, into which is inserted the lower end of a pipe 32 feet high, equal to the pressure of one atmosphere, the upper end of which pipe is placed in a cistern; this cistern is in communication ahove and below by pipes and valves with a second cistern, in which is a float. The lid of the second cistern is iu communication with the cylinder of a steam engiue. Tbe lower end of tho second cistern is in communication through a valve with the hot well aud with the lodge. When the water from the first cistern enters the second cistern the float rises, and the water from the lodge keeps the well at the same level. When the steam from the cylinder of the steam engine enters tho second cistern it lowers the float and drives the water into the hot well and back into the lodge; the steam from the second cistern then passes through the top valve into the first cistern and is there eondensed; the partial vacuum thus formed then raises more water from the well, and the operations are repeated as before. In the lid of the first cistern is a pump to draw off the air, and this pump is used to fill both the cisterns with water on commencing work. Between the lodge and the well is a turbin, or a water wheel, or other hydraulic engine, to make use of the fall of water between the two levels.

Old and New Objects of Invention.—The inventions of the last hundred years sometimes appear more grand and far reaching than any now being developed or demanded. But it must he remembered that the old inventors had a clear field. Everything was demanded and nothing was done. The steam engine, the cotton gin, the telegraph, smelting with pit coal, the hot blast, the rifled cannon, aud all the other great inventions which have ehanged the whole aspect of life, were then unknown, and even the most imperfect development of them was more striking and revolutionary than the later and really more valuable refiuements of the same inventions. And it does not follow that less useful work is wanted or likely to he done now. On the contrary, the improvements in steam power, for instance, likely to be developed during the next hundred years, will have a greater money value than all tbat has preceded—perfect as the steam engine is to-day. The old inventors were called upon to discover and open the doors of Nature's storehouse; the later inventors are called upon to hring out and set in order her wonderful secrets.

Shipbuilding in the United States.—The following statistics show that the shiphuilding industry is not quite extinct in this country: During the fiscal year ending June 30th, 1878, 32 iron vessels were built, with a tonnage of 25,960.29 tons. This record is second to the hest record the country has yet made, which was in 1874, when the tonnage aggregated 33,097 tons. The next best record in tonnage was in 1873, when it amounted to 26,548 tons. The number of iron vessels built during the past year was greater than in any other year, the year which most favorably compares with it being 1873, when 26 were built. Of the vessels built during the past year, 9 were ocean propellers, varying in tonnage from 1,156 tons to 3,548 tons; 1 was a lake propeller of 306 tons; 1 was a stern-wheel river steamer of 1,028 tons; 7 were side-wheel river steamers, ranging from 128 to 1,285 tons; 13 were steam tugs, the largest of which measured 180 tons; and the remaining vessel was a yatch. The current year promises to surpass the last cousiderbaly in its additions to our iron shipping.

Working up Iron and Steel Shearings.

Thin shesrings or pieces of iron or steel—such, for examplo, as tho scrap from cutting iron sheets for tin-plate making, and from other operations in which thin sheet iron or steel is employed—are frequently reworked with other metal either in the puddling furnace or in the retining furuace. In some cases the scrap has been placed loose in the puddling or refiuery furnace, but more commonly it is made into bundles. In any ease the binding only serves to keep the material together whilst heating up, for the bundle then falls apart, allowing the metal to mix with the remaiuder of the chargo upon the bed or hearth of the furnace. There is much loss in this process of reworking, 30 cwt. of this scrap not producing more than a ton of manufactured metal. Accordiug to tho invention of Mr. J. H. Rogers, of Llanelly, the shearings or waste pieces of thin iron or steel are compacted together into masses or blocks, and these, either alone or together with other pieces of iron or steel, are placed in a rehcating furnace, and, when heated to a proper temperature, are cousolidated under a steam hammer or in other conveuient wsy. In this manner he can obtain a ton of manufsctured metal from 23 cwt. of shearings. In order to form the shearings or pieces of iron or stesl into masses or blocks ready for heating, he places them in a box or mold, and by a steam press or other suitable machine he presses the contents of the box or mold until a compact block is obtained. The mass thus compacted is withdrawn from the box or mold hy an opening provided for the purpose, and which is closed by a door whilst the material is being molded. The compacting of the scraps is performed in a cylinder or mold, wherein they can be compressed by a kind of steam hammer. To discharge the molded mass or block, the box or mold is opened, and by means of a bar inserted at a suitable hole it is forced out in a condition to go into the reheating furnace. In the furnace, and in the subsequent hammeriug, the blocks or masses are treated in the same way as piles or blooms.

Paper vs. Iron Car Wheels.—According to the Cbicago *Railway Review*, the average running capacity of an ordinary iron car wheel is about 75,000 miles; while that of a paper wheel, with a stcel tire, is from 450,000 to 550,000 miles. Iu order to get this wear, it is necessary to give the tire from three to four turnings. The first cost of the paner wheel is $65, and of the best quality of cast iron wheel $14. The mileage of tbe latter is usually guaranteed at 50,000 miles. The cost of turning the steel tire is $35, which may safely be estimated as equal to the cost of the more frequent renewals of cast iron wheels with the attendant expenses of transportation in each case. The paper wheel costs $65, and runs 450,000 miles in 2.8 years. For convenience in reckoniug, and at a disadvantage to the paper wheel, on account of the interest money, call this period three years. At the end of this time the original cost, with 7% compound interest, amouuts to not quite $80. But during this period niue cast iron wheels have been used, costing $14 each. Allowing a rebate of $5 each for the worn out wheels, and calculating on simple interest at 7%, the cost of the wheels for this service amounts to $91.50, showing a saving in the case of paper wheels of $11.50, and were compound interest computed, as in the case of the paper wheels, the saving indicated would be a much larger amount. In computing the cost for the second period of three years a much greater saving would he shown, since a renewal of the tire only, at a cost of $35 is necessary, instead of a first cost of $65 for a new paper wheel. The data from which this conclusion is reached are vouched for by the Pullman Company. Tbe *Review* adds that the experience of the railway companies which have used the paper steel tired wheels bears out the records of the Pullman Company. As engine truck wheels the paper wheels seem to he especially successful, the experience on some roads warranting the couclusion that they will make 800,000 miles before the tire requires renewal.

Artificial Marble Producen by Steam Heat and Pressure.—A process has been invented hy Miss Hosmer, the sculptress, for making artificial marble which differs from previous processes in the fact that limestone in the solid state is employed as the base instead of a mixture of plaster and cement. The limestone is worked by any suitahle means to the desired form, and is then placed in a boiler furnished with a safety-valve aud manometer, so that the pressure therein may be noted and controlled as may be required. The boiler is filled with pure water at the ordinary temperature, care being taken that there is no mineral deposit introduced with the water, and that the water completely covers the objects placed within the boiler. The boiler is then hermetically sealed, and fire applied, and the water allowed to boil until the manometer indicates 75 pounds of atmospheric pressure if the objects are small, and 90 or 100 pounds of pressure if the objects are large. When the heat reaches the above-mentioned point the water is allowed to cool until the pressure indicated by the manometer returns to zero. The water is then taken out of the boiler either by means of a pump or a syphon, and the objects are removed from the boiler preparatory to heing placed in the alum or colored bath, various recipes heing given for different colors.

SCIENTIFIC PROGRESS.

The Telectroscope.

M. Senlecq, of Ardres, bas recently submitted to the examination of M. Du Moncel and Hallez d'Arros a plan of su apparatus intended to reproduce telegraphically at a distance the images obtained in the camsra obscura. This apparatus will be based on the property possessed by selenium of offering a variable and very sensitivo electrical resistsuco according to ths different gradations of light. The apparatus will consist of an ordinary camera obscura, coutaining at the focus an unpolished glass, and any system oi autographic telegraphic transmission; ths tracing point of the transmitter intended to traverse tho surface of the unpolished glass will be formed of a small piece of selenium held by two springs acting as pincers, insulated and connected, one with a pilo, the other with the line. The point of sslenium will form the circuit. In gliding over the eircuit, more or less lightened up, of the unpolished glass, this point will communicate, in different degrees and with great sensitiveness, the vibrations of the light. The receiver will also be a trscing point of black lead or pencil for drawing very finely, connected with a very thin plate of soft iron, held almost as in the Bell telephoue, aud vibrating before an electro-magnet, governed by the irregular current emitted in the line. This pencil, supporting a sheet of paper so as to receive the impression of the image produced in the camera obscura, will translate the vibrations of the matallic plate by a more or less pronounced pressure on that sheet of paper. Should the selenium tracing point run over a light surface, the current will increase in intensity, the electromagnet of the receiver will attract to it with greater force the vibrating plate, and the pencil will exert less pressure on the paper. The line thus formed will be scarcely, if at all visible; the contrary will be the case if the surface he obscure, for the resistance of the current increasing, the attraction of the magnet will diminish, and the pencil, pressing more on the paper, will leave upon it a darker line. M. Senlecq thinks he will succeed in simplifying this apparatus hy suppressing the electro-magnet, and collecting directly on the paper by means of a particular composition the different gradations of tints proportional to the intensity of the electric current.—*London Times.*

Something Curious about Explosives.—A remarkahle accident happened not long ago to M. Zede at the Normal school in Paris. He was studying the properties of a composition formed of equal parts of gun-cotton and nitrate of ammonia. This was inflamed in a bronze tube of six millimeters internal diameter, and expanded without detonation. Thirty experiments had been made, and M. Zede then reduced the size of the tube to five millimeters. When he tried the experiment anew under these conditions a frightful explosion occurred. The tuhe was shattered into 60 pieces, some of which passed through the roof of the laboratory and penetrated about four centimeters into a brick wall. The operator had one of his legs broken. This accident is engaging the attention of the French Commission des Poudres et Salpetres. M. Sainte-Claire Deville, in the Academy, pointed out that the fact belonged to a category including already several others, and he recalled an observation by Prof. Abel. Ahout 0.2 grains of chloride of nitrogen is placed in a watch-glass, and exploded with a piece of phosphorus; the noise is tremendous, but the explosion has little or no shattering effect. Now repeat the same experiment, after having breathed on the chloride so as to deposit a thin envelope of moisture, which cannot he more than a thousandth of a millimeter thick. In this case the explosion is less noisy, hut the effects are quite different. Not only is the glass pulverized, hut the tahle supporting it is perforated.—*Boston Journal of Chemistry.*

Powders Solidified by Pressure.—A Belgian scientific journal describss some interesting experiments lately made hy M. Spring, who bas subjected a number of finely-divided substances to a pressure calculated to be eqnivalent to 20,000 atmospheres. Potassium nitrate and sodium nitrate were generally converted into a perfectly homogeneous mass, which was harder and denser than the fused salt, and was translucent like porcelain. Sawdust exhibited a "slatey" cleavage and had a density more than three times that of the wood from which it was made. The author points to these experiments as having estahlished the possibility of causing cohesion of solid bodies by the application of great pressure, unmindful of the fact that what are called dusttiles are largely manufactured by this very method. How far the effects of simple pressure are taken into consideration hy geologists in their study of the solid layers of the earth's crust is open to question.

Potassium.—As a lecture experiment Dr. Erckmann, introduces a pieee of potassium, of the size of a pea, into a small test tuhe, heats to fusion, turns the glass round and round till the metal congeals, and then seals up the tube. The greater part of the potassium is deposited on the sides of the tuhe as a specular metallic coating, resembling silver, and can be exhibited during lectures, etc. The other alkaline metals may he similarly treated.

Geological Changes in Progress.

In the *Popular Science Monthly* Prof. J. S. Newberry told us lately thst various facts indicate that the coast of New Jersey and Long Island is gradually sinking. From the marshes of New Jersey are taken the trunks of trees which could not have grown there except when it was drier grouud, and on the shore stumps are seen now under waters of trees which must have grown on land. So, too, the sea throws up in storms portions of turfy soil, once covered only by the air, and similar soil has been reached below the sea level, in pits dug through drifted sand along its margin. Ths land boundaries have been changed and farms diminished, even where the wash of the shore wavss produced no effect. Ths rate of this subsidence is very slow—only a few inches in a century—and it may at any time bs arrested and reversed; but should it continue, as it may, for some thousands of years it would result in a submerging of land now valued at hundreds of millions of dollars and a complete change of position in the seats of commerce and industry, which must always center about this harbor. This possible catastrophe is, however, so uncertain and remote, that it seems hardly sufficient to disturb the equanimity of at least the present generation of inhabitants.

Dr. Gessner in a late letter to the London Geological Society, alluding to the same clase of phenomena, states that in New Brunswick, at St. John's, the land has been elevated, at the Grand Manan Island and the Great Tantamau Marsh, there has been subsidenee; at Bathurst, and on the opposite coast of Lower Canada, the land seems to be rising; in Nova Scotia, near the Bay of Fundy and Mines Basin, thsre is subsidence; but, on the southern side, there are signs of elevation, the sea also rapidly encroaches on Louisberg, in Cape Breton, and in Prince Edward Island, likewise submergence of the land is seen to be taking place at Nantucket, Martha's Vineyard, and Portland, submergeuce of the land is proceeding, locally, at the rate, probably, of four feet in 60 years.

New Instrument to Determine the Presence of Metals in Ores.

At a recent meetiug of the Philadelphia Academy of Natural Sciences, Prof. George A. Koenig, of the University of Pennsylvania, exhibited his recently invented "chromometer," an instrument designed for the purpose of making exquisitely delicate determinations of the presence of certain metals in ores. It is based upon the optical fact that complimentary colors will extinguish each other if mingled in proper proportions; for instance, if to a green solution a red solution be added, the liquid, if the proper conditions be complied with, will become colorless. The speaker had applied this principle to the colors which certain metals, as iron, manganese, copper, etc., produce when fused with horax, which is the only chemical used in this method of analysis. He prepares such glasses or beads containing known quantities of a metal in one hundred parts, and observes how thick a glass of the complimentary color must be to produce extinction. To accomplish this the instrument ie furnished with a glass wedge of a green or red color, cut at an angle of about one degree. By moving this wedge before the glass bead, with the help of a suitahle rack movement, a scale moves at the same time, and when the point of extinction of color is arrived at, the reading of the scale refers to a table showing the percentage of metal contained in the examined substance. By this method of analysis a correct determination of manganese in an iron ore can he made in 15 minutes, which is not more than one-third the time required hy the usual methods of analysis.

The New Metals.

Gallium—Lecoq de Boisbaudran and E. Jungfleisch have published in *Comptes Rendus* some more notes on their examination of the properties of this newly-discovered and curious element. The metal crystallizes in octahedra with the summits of the pyramid cut off by a plane, in some cases truncated so as to give the crystals a tabular form. The metal is hard and only to a small degree malleahle, although thin plates may be bent backwards and forwards many times without breaking. A ray of light which has been reflected several times from bright surfaces of the metal acquires a fine bluish-green color.

The New Metal Philippium—Mr. W. G. Brown, of the East Tennessee University, writes to the *Chemical News*, that while analyzing *sipylite*, a year or more ago, he observed, with tbe spectroscope, certain lines, one at least of which appears to belong to the new metal philippium, and indicates the presence of that element in sipylite.

A Rare Mineral.—Mr. Edward Goldsmith exhihited, at a late meeting of the Philadelphia Academy of Sciences, a specimen of asphaltum found 16 feet helow the surface in a bed of cretaceous marl near Vincenttown, N. J. In the same bed and within a few feet of the asphaltum was found a yellow mineral resiu of the nature of krantzite (first described by Bergeman as occurring at Nienberg, Germany), a species of amber, and containing small white crystals, believed to be succinelliuite. This is the first time that either of these minerals has been found in New Jersey.

Mining Share Market.

We have had a comparatively strong, firm week in stocks, but toward the close there was a slight falling off in the prices. The live opening of the week was sudden and unexpected, for up to that date the market had been apathetic and insipid.

The feature of the market was the move in Belcher, which relieved the monotony of operations in Virginia shares, advancing nearly a dollar. This advance was kept firm till the latter part of the week, when it slightly shaded off in sympathy with other stocks. There has also heen some excitement in Bodie mines, the Blackhawk, Bechtel and McClinton receiving the most attention. The rise was too unhealthy to be lasting, however, and on Wednesday they took a tumhle and are rapidly seeking the figures from which they were so suddenly called. The distrust and uncertainty concerning the Sutro compromise, has had a tendency to weaken prices somewhat, though the news of the late definite settlement has produced a better feeling in the market. The mines all over the State are peculiarly active, the late rains making water plentiful and work possible both for quartz and placer claims.

Silver-Plated Amalgamated Plates.

The following letter from a well-known manufactnrer of silver-plated amalgamating plates for miners' use will be of interest, explaining as it does the action of these plates:

Milton Kelly, Esq., Boise City, Idaho:—Dear Sir: In a recent copy of your paper I noticed an article stating that ordinary copper plates would prove as serviceahle in saving gold as the silver-plated plates. Such has not heen the result either on Snake river or in placer or quartz mining in California, as I am constantly receiving orders for *silver-plated* plates to replace the copper plates.

The comhination of metals, silver, copper and quicksilver, creates a chemical and electric action, causing a greater attraction for gold than copper and quicksilver alone combined.

The proper test, and it has been tried, is to have one sluice lined wiih copper and another with silver-plated plates, of the same surface. The result has always proved vastly in favor of *silver-plated plates*. The copper plates will, in time, ahsorb considerable gold, but it only accumulates in spots, and very unevenly, leaving some parts of the copper bare. Upon the parts not covered with gold verdigris forms, causing a great deal of labor and trouble.

The advantage of silver-plated plates is that gold can be saved immediately, giving miners the benefit of all the gold deposited in the amalgam, while with copper plates it is absorbed in the copper, and can only be made availahle hy smelting or going through chemical process.

If parties contemplating mining on Snake river will supply themselves with a good quality of silver-plated plates, protect them well from houlders and gravel by screens, and he careful in removing the amalgam, they will have no cause to regret the investment. Miners in the Snake river country should he careful to avoid purchasing inferior qualities of plates, as several parties have had their plates replated at my estahlishment.

Full particulars regarding price and working of these plates freely furnished to any one on application. Yours, truly,

E. G. Denniston.

San Francisco, March 9th, 1879.

Bullion Shipments.

Since our last issue, we have noticed the following hullion shipments:

Hillside, March 13th, $4,840; Tybo Con., March 10th, $8,030.38; Star, March 16th, $14,-400; Christy, March 17th, $5,208; Standard, March 15th, $18,794.99; Martin White, March 16th, $8,314; Bulwer, March 16th, $16,506.08; Northern Belle, March 15th, $9,710.03.

By the fall of a gallery in Gilmore's Garden, at New York, many persons were injured and a frightful panic ensued.

Complete success has attended the French Ministry's opposition to the De Broglie-Rochebonet impeachment.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Items from Oleta.—*Ledger*, Mar. 15: With plenty of water mining industry around Fiddletown has taken a decided start. S. H. Clarke's cement claim is running to the full capacity of the 10-stamp mill to dispose of the gold-bearing earth. From 12 to 16 men are employed constantly. The American Flat Gravel Company's claims are in full blast. The Oleta Gold mining company is the name of a corporation lately formed to operate near Fiddletown. It is to prospect for gold-bearing quartz east of town. Surveyors were set to work in the early part of the week to pave the way for a thorough exploration.

Miscellaneous.—Mr. Dakin has commenced mining operations at Butte mountain. He has plenty of capital behind him to explore the center of the elevation. The plan of operations is to run a tunnel from the side of the mountain. A clean-up was made at the Talisman mine, near Amador City, lately. It paid well. The prospects of the company are more encouraging than they have been at any time since its incorporation.

Mining.—The Illinois quartz mine, two miles north of Plymouth, owned by George Bowden & Co., looks as if it had all the requisites of a good mine. The shaft is down 12 or 15 ft, with a well-defined ledge six ft in width, and fine gouge on the foot wall. Some of the rock has prospected as high as from five to ten cents to the pan. The discovery of this claim has given quite an impetus to prospecting. Quartz claims are being located all around, and the general opinion is that the excitement will lead to the opening up of some permanent mines. The Hercules shaft has been deepened from 25 to 30 ft since they commenced sinking. Some trouble is experienced with the water, especially since the late heavy rains. At the Phœnix things are moving along at the usual gait. Timbers are getting scarce in the yard, but a large number are expected to be floated down shortly. Report says the rock in the mine is as rich as ever. Miners are busy filling up the slopes with waste dirt to prevent caves.

CALAVERAS.

Gravel Mines.—*Chronicle*, Mar. 15: At the Duryea mine, hydraulicing is being prosecuted with vigor. Work is now being prosecuted in the extreme northern end of the claim, a new tunnel having been run for the flume, and the necessary ground sluices cut. The Duryea hydraulic has a pressure of 250 ft, uses from 300 to 500 inches of water, sports a three-ft flume, and goes it on a big scale generally. With the superior facilities for working, an immense amount of gravel is daily put through the flume. The Happy Valley Blue Gravel and Hydraulic mining company's claim on Sport hill is being worked as fast as possible; 500 inches of water are used under a heavy pressure. A three-ft flume conveys away the debris and it is filled to its utmost capacity all the time. A water-power derrick is to be put up in the mine immediately, the quantity of cement encountered rendering it indispensable. No clean-up has yet been made, active operations having been in progress but a short time. George Emerson, the well-known hydraulicist, is Superintendent of the mine. Work is in progress on the tunnel of the Happy Valley Blue Gravel and Hydraulic mining company; a bore that is to extend 2,200 ft through solid bedrock. It is already in 100 ft and expanding as fast as muscle and powder can make it. The rock is getting quite hard—a blackish kind of slate. Mr. W. H. Curnow, a practical miner, in superintending the tunnel proceedings. There is talk of putting a diamond drill, to be run by compressed air, into the tunnel. The Maison de Sante hydraulic, W. W. Cook, proprietor, is being steadily worked, a large force of hands being employed. The gravel looks first-rate. No clean-up has been made this season.

MARIPOSA.

Ferguson Notes.—Cor. *Gazette*, Mar. 15: The prospects of the Ferguson mine are growing brighter every day. They make regular clean-ups, and have commenced to run the north drift at the second station. The ledge is two ft wide, and shows well in free gold and sulphurets. The stopes all look well, with an abundance of gold in sight. The company is going to add 10 more stamps soon, which will be 20 in all, build a water-wheel, erect a compressor, and prepare to sink the No. 2 shaft. At the mouth of the tunnel the rock is coarse but pays from $75 to $100 per ton. This rock comes from the bottom stopes, where there is an abundance of this rich ore. The Virgin Hill Co. is pushing its work, and when the tunnel strikes the ledge and connects with the shaft, they will commence taking out rich rock. The Cranberry is a good mine, and carries with it a well-defined ledge seven feet wide. It pays $10 per ton.

MONO.

Bechtel.—*News*, Mar. 16: On the 400 level, 280 ft south from shaft, after leaving the old Bechtel ore body, the porphyry horse, which has been a nightmare during the past winter was passed through, and a development made in a fine body of ore which averages two ft in width. The new strike has been prospected a distance of 50 ft south, and shows the same width the entire distance. The foot wall of the Bechtel is found pitching east at an angle of about 55°, the strike of the vein being a little east of south. The developments made show an entirely new and hitherto unprospected chute of ore, as the levels above and below have never reached the distance now attained south. The ore now being extracted differs from that formerly found in the Bechtel workings in the fact that it is free from manganese and the glassy, hard quartz found elsewhere. Assays from the new find taken across the face show from $00 to $75 as an average.

Tioga.—Excavating for 520 station. East crosscut on 420 level is now in 125 ft, with no important change to note. From north drift on 320 level the east crosscut is in 50 ft, and the ledge looks promising in the extreme, being two and a half ft in with. West drift on same level is in 240 ft with no material change to mention.

Standard.—North drift from main shaft to connect with incline is in 43 ft. The ledge is two and a half ft wide and looks well. The south drift is in 268 ft; progress during the week 12 ft. The ledge is three ft wide, with good average ore. The ledge in the upraise in this drift is four ft wide and is looking very well. North drift from east crosscut, 300 level, is in 125 ft, showing a ledge 18 inches wide of good ore. North drift on West Standard is in 128 feet. The ledge is two ft wide of very fine ore. A winze has been started on the West Standard ledge, 200 ft from the south line. This winze is down 10 ft, showing a ledge 18 inches wide of very rich ore. The drift on the Cook ledge is in 200 feet from the south line; the ledge is two ft wide and of good average ore. The stopes all looking well.

Black Hawk.—On the 220 level the south drift is now 20 ft in length and the north drift 15. The ledge on both faces looked quite as strong as at any point since the ledge was struck. At 320 level a station has been cut and a crosscut west has been commenced, and a distance of 70 ft will have to be run to demonstrate the existence of those ledges which have already created so much excitement. New buildings are being erected over the shaft.

Summit.—Drifts being advanced on the ledge both north and south in the incline shaft, and pushing said shaft down to connect with the 450 level in the Standard, at which point the Summit ledge has been cut.

Mono.—Crosscutting on the 400 level. The east crosscut is in 18 ft, and the west 12 ft. The ground in face of east crosscut is broken. Work has been resumed on the 260 level, and a crosscut east has been run 180 ft. The flow of water remains unchanged, about 40,000 gallons being hoisted every 24 hours.

MONTEREY.

Carmelo Coal Mine.—Castroville *Argus*, Mar. 14: There is great activity at the mine itself and in the construction of the railroad between the mine and Strader's landing. About 25 Chinamen are employed in grading the road and probably 50 white men in the mine, at the saw-mill and in building trestle work for the railroad. A store has been opened at the landing with the view of supplying the wants of the people at and near the mine, and of all the settlers in that region as well. The mine is considered a very valuable property, the coal being of good, marketable quality and found in quantity sufficient to fully justify the extensive outlay involved in the construction of the four-mile railway, erection of the saw-mill, etc. The railroad will be completed this spring, so that it will not be long before frequent and regular shipments of coal will be made from Strader's landing.

NEVADA.

Notes.—*Foothill Tidings*, Mar. 15: The depth of the Watt shaft is 417 ft. A tunnel has been run east a distance of 1,315 ft, and a western drift commenced which has progressed 50 ft; from the eastern drift are winzes Nos. 1, 2 and 3 at various points. The Scadden Flat works have had all they could conveniently do in pumping, and hoisting was for a time suspended. The contractors on the new shaft of the Washington mine are making rapid progress; 2,120 shares more of the working stock have been offered for sale at 25 cents per share, payable in four installments. At King's hill the incline shaft is sunk 250 ft, and a drift run south 105 ft. The ledge is from 8 to 18 inches in thickness, and gives good paying quartz. The last crushing of rock was 35 loads, which yielded $65 per load without including sulphurets. There are now about 30 loads on the dump. The ledge in Rocky Bar is 4 to 10 inches, and uniformly good. Several companies of tributers, in all 15 to 20 men, are working through the south shaft. Three different lots of tribute rock recently crushed, paying respectively $58.50, $34, and $22 per load. In addition to the tributers, the company has 30 underground men employed. Chief of the Hill, south end of Osborn hill; the shaft and incline down 91 ft; the bottom in hard blasting ground, with a handsome ledge of from 8 to 10 inches in width. Copper ore is now being extracted from the 150 level of the big copper mine at Spenceville, and appears to be inexhaustible in quantity, as no walls to the vein have yet been discovered. In the Pittsburg the 600 north drift has been run a distance of 10 ft. The lode in the latter drift presents well, and is yielding good ore. The 800 north drift has been run six ft during the past week; this drift is also yielding good ore. All the stopes are producing well. The mill is running up to its capacity on company ore.

PLACER.

Mining Items.—Cor. *Democrat*, Mar. 15: Work is still being carried on at the German mine, with even better success than expected. Capt. Staples has a force of men on the North Springfield lead, known as the Old Miner. A clean-up was made at the Tingman last week, which amounted to something less than $2,000. On Big Canyon there is quite a force of men at work on the Lucky Baldwin mine. It is paying a good percentage over expenses. The Pocahontas, at Logtown, has not been doing much of late, but they have concluded to begin sinking in the shaft again. The sinking is to be sub-let to contractors. The big spur wheel at the South Shaft hoisting works of the Springfield was broken by the pump on the lower level, and on account of the delay occasioned, so much ore has not been hoisted as common, as an extra water bucket was put on in place of the ore bucket, but the pump is in running order again, and no more trouble is anticipated.

SIERRA.

Forest City Notes.—Cor. *Messenger*, Mar. 15: The air shaft of the North Fork company has caved in for over 50 ft, and until it is repaired all labor must necessarily be suspended in the tunnels and breasts, which is rather unfortunate at the present encouraging stage of affairs. On March 11th the Bald Mountain Extension tunnel, Watson Bayles, contractor, was in 400 ft, who is now blasting talcose slate or serpentine rock with from three to four pounds of Giant powder per day. Average speed at present, five ft with two shifts of two men each. Good air is brought into the tunnel with a water blast through an iron pipe, which will soon be connected with air boxes further underground. Thickest stratum of rock, 12 ft; in all as run only 50 ft has been pierced.

TRINITY.

Bullychoop & Occidental Co.—*Journal*, Mar. 15: At a meeting of the above company, held in Weaverville, 21 of the 28 shares in the mines were represented. From report it appears that the tunnel is now in a distance of 160 ft. A contract was given to John B. Siegfried to drive it 125 ft further at $6 per ft, the company furnishing powder, tools and light. The tunnel is five ft in width and six ft high. It is expected that one or more of the several lodes embraced in the company's location will be struck by the tunnel within the 125 ft additional contracted for. After this is completed, 325 ft more of tunnel will be necessary to reach the Occidental, which is considered the main lode. An assessment of $80 to each 1-28th interest was levied, payable on the first Monday in May. This amount, when collected, will pay all the company's indebtedness to that date and leave a balance in the treasury with which to do more work. It was also decided at the meeting to take active measures to collect whatever assessments are delinquent at the earliest possible date. Since our last report 125 tons of rock have been run through the arastra, from the Bullychoop lode, yielding at the rate of $16 per ton.

NEVADA.

WASHOE DISTRICT.

Gould & Curry.—Gold Hill *News*, Mar. 20: The joint Best & Belcher east drift, 1700 level, is reaching toward the perpendicular of the Osbiston shaft. The retimbering of the shaft was completed to-day. Sinking at the Osbiston shaft has been stopped for the present on account of water. It has attained a depth of 515 ft. Since work was stopped, the water has raised to the 440 level, where it remains stationary. The drain tunnel is in 75 ft and has still 300 ft to run to reach the shaft.

Belcher.—The main incline has reached a depth of 2,650 ft. The south drift, 2560 level, is being extended six ft per day, and has its face now 285 ft from the incline. Work in the south drift, 2360 level, has been resumed, and it is being pushed toward the south line.

Bullion.—Work in the crosscut, 1840 level, has been suspended temporarily to put the pipe for the new compressor into the shaft. Repairs to the shaft have also been discontinued. Foundations for the compressor are being laid.

Overman.—The drift north on the 1600 level shows no change of formation. It is skirting the vein, sometimes cutting into the black dyke and sometimes running entirely out of it. The winze from this level is down 125 ft.

Con. Virginia.—The repairs to the shaft below the 1400 level are progressing well. The main drifts connecting with the C & C shaft on the 1500 and 1600 levels are still being repaired. The joint Best & Belcher crosscut on the 1950 level has been stopped. The joint California winze has been sunk and timbered to the depth of 78 ft. The joint north drift from the west drift, 2150 level, is now in 86 ft. The average yield of ore per day is about 245 tons.

California.—The repairs to the Con. Virginia shaft are being pushed to an early completion. The joint Consolidated winze from the 1950 level is being sunk at the rate of two ft per day in hard blasting rock, and has attained a depth of 78 ft. The joint north drift from the west drift, 2150 level, is averaging four ft per day. Sinking at the C & C shaft is now making three ft per day in hard rock.

Justice.—Crosscuts Nos. 5, 6 and 7, west, on the 1300 level, are still progressing in favorable vein matter. The usual repairs are being made to the incline and drifts. The surface shaft, south, near the Waller Defeat shaft is yielding 20 tons of very fair ore per day. A small donkey engine is to be placed there which will do away with the windlass and extract the ore at a cost of $1.50 per ton.

Ophir.—The main shaft is receiving needed attention above the 1405 level. The joint Mexican upraise from the 2100 level to connect with the 2000 north drift is still passing through hard blasting porphyry, and averaging three ft per day. The incline is now 130 ft, on the slope, below the 2200 level. The stopes on the 1900 and 2000 levels continue their average yield of high-grade ore.

Sierra Nevada.—By the connections in the drifts on the 2200 level, connecting the incline and the east shaft, and between the 1700 level and the North Con. Virginia shaft, the ventilation of the whole mine is much improved. The incline is in cap rock still showing lively veins of quartz which yield low assays.

Julia Con.—The 2000 level has not yet been freed from water. The pumps are running regularly, raising water to the surface. The pipe connecting with the Sutro tunnel is not large enough for required use. Operations have been resumed in the winze from the 1800 level, and are making better headway than usual.

Leviathan.—The face of the south lateral drift on the 750 level has run into favorable ground, consisting of quartz with streaks and spots of low grade ore. Good stringers of ore continue to cross the north lateral drift on the same level.

North Bonanza and Flowery.—Lateral drifts have been started on the 300 level north in North Bonanza ground and south into Flowery. These are making excellent headway and skirting the ore vein. No change has been encountered in the north drift from the 200 station.

Utah.—Sinking the incline is making good progress The two water tanks in the incline have been completed ready for use. The compressor has been overhauled, and all the machinery is in good condition.

Solid Silver.—The main tunnel has passed entirely through the caved ground at the north end. It is well secured, substantially timbered, and sufficiently widened to admit of a side-track for ore extraction when required.

Sutro Tunnel.—The compromise with the mines has been effected. A very large force of men—reported to be 1,200, in three shifts of 400 each—will be now immediately put to work on the sub-drain.

Hale & Norcross.—The winze from the 2000 east drift has reached the Savage 2100 level. The pumps are holding the water below the 2000 level, and running steadily.

Mexican.—The joint Union Con. winze, from the 1600 level, is averaging two ft per day in hard birdseye porphyry. It is being sunk on the slope; it is in 290 ft on the incline. The main north drift on the 2000 level is approaching the Union Con. line at the rate of six ft per day, in a fine soft vein formation showing considerable quartz. The joint upraise from the north drift 2100 to reach the 2000 level is averaging three ft per day in hard, blasting porphyry.

Union Con.—The flow of water from the 1600 level east drift has decreased to two miners' inches. The joint Mexican winze, 1000 level, is increasing its depth two ft daily, and is down 290 ft on the incline. The Mexican north drift on the 2000 level, is making six ft per day through soft vein matter, showing some fine quartz.

Chollar-Combination Shaft.—The air compressor will be in position soon. The pumps are discharging about 100,000 gallons of water daily into the Sutro Tunnel.

Yellow Jacket.—The eight-inch pipe for the compressor is in place. At the the old shaft the work of taking out the pump column is still going on.

Lady Bryan.—Work on the 380 level and north on the 000 level has been stopped for the present. The south drift on the 600 level is progressing as usual in fine-looking quartz.

Alta.—The north drift on the 1550 level, continued as usual along the vein. The joint Benton double winze is 150 ft below the 1550 level on the slope.

Silver Hill.—The main incline continued on down as usual. The crosscut east from the 1100 level is making five ft per day in a soft formation of clay, quartz and porphyry. There has been a slight increase of water of late, but not enough to interfere with work.

Best & Belcher.—Joint Gould & Curry crosscut No. 1, 1900 level, is cutting hard porphyry and is in 83 ft. West joint Consolidated crosscut No. 3, 1900 level, is in 104 ft, and has been stopped as useless for fear of tapping water.

BELMONT DISTRICT.

Belmont.—*Courier*, Mar. 15: All work at the mine has progressed satisfactorily with good results during the week; have advanced the south raise 20 ft in ore assaying from $100 to $300 per ton, which is the best evidence that can be had of a good body of ore in this part of the mine. Will have about 25 ft more to run to make a connection. The vein matter in 300 level drift is soft which will enable the workmen to get along faster. The stopes are without change, and are yielding the usual amount of rich ore. Number of tons extracted for the week, 17; average assay, $113.

Highbridge.—Have advanced the lower north drift 36 ft; the face looks very favorable for ore. As work advances south toward the Belmont, indications are that there will be a larger body of ore in this part of the mine than was anticipated. The stopes in the upper workings continue looking well and furnish the usual quantity of ore. At present there is in the dumps and ore houses 500 tons of ore ready for the mill. Everything in connection with the mill running as well as usual.

Gila.—The crosscut from 200 level has been driven 19 ft, and the crosscut from winze, 23 ft, making the length of the former 391 ft, and the latter 64 ft. No ore of any value has yet been found in either of these openings, but the indications in both are good for soon striking a body of ore. The stope in the south drift has improved very much. It has increased in length from 45 ft of the distance exposed in the south drift when running it to 75 ft, and no doubt will be as long again and very probably longer. The average width of the vein for the entire length of the stope is about three ft, part of which, a streak on the footwall of about 12 inches, is very rich, assaying from $300 to $700 per ton. The entire vein will average fully $100 per ton.

DANVILLE DISTRICT.

Notes.—*Courier*, Mar. 15: Good progress is being made in developing the Boston and Richmond mines. The veins are very much broken and carry free milling ore of a high grade. In the Sagehen and Trippell mines the prospects of striking good ore are very flattering. Very little work has as yet been done on the locations south of the canyon, but the indications are favorable for finding a paying ledge. The Danville company and St. Louis company are now trying to perfect the necessary arrangements for running a joint tunnel 1,200 ft or 1,300 ft in Mineral hill, at which distance they expect to tap the main ledge at a depth of 450 ft below the surface.

EUREKA DISTRICT.

The Richmond.—*Sentinel*, Mar. 15: The recent development in the Richmond hardly deserves to be characterized as a new find. It is more in the nature of an extension of an ore body hitherto known to exist. It occurs between the fourth and fifth levels, and seems to extend toward the surface. The development is important in this, that it was not altogether expected that ore in quantity would be met with in this particular quarter. The whole mine is looking quite as well as at any time in the past.

The Hamburg.—The intermediate drift has advanced 22 ft, and is now within 23 ft of the upraise from the end of the south drift of the 450 level. The vein of ore followed shows some little improvement. The east crosscut of the 459 level has been continued 13 ft, making a total of 30 ft. The face is in vein matter, with bunches of low grade ore. In the 600 level the west crosscut has been advanced 10 ft, making a total of 179 ft from the main south drift. There is no material change to note. The south drift has been advanced nine ft, making a total from the west crosscut of 116 ft, with the face in unusually hard rock. The winze was sunk 17 ft, making a depth of 80 ft below the 600 level. The bottom is in very favorable vein matter.

The Jackson.—The following work has been done: Main south drift (crosscut) has been run 11 ft; total, 36 ft. Southeast drift has been advanced 11 ft, making 90 ft from the ore chute. Fourth level drift has been run 25 ft; total, 31 ft. The ore chamber continues to look well, especially the east drift, which is now in 60 ft. Intermediate drift, 30 ft below the ore chamber, also shows good ore. Will probably make connection with the ore chamber during the week and afford better ventilation. Everything in and about the mine is running smoothly.

[Continued on Page 188.]

The Mining Debris Question.

Full Text of Judge Keyser's Decision.

In the District Court of the 10th Judicial District, of the county of Sutter.

James H. Keyes plaintiff, vs. Little York Gold-Washing and Water Company (limited) et al., defendant.

Findings of fact and conclusion of law:

The above cause came on regularly for trial at the June term, 1878, of this court. The plaiutiff appeared by George Cadwalader, P. Van Clief and J. H. Craddock as his attorneys, and the defendants appeared by S. M. Wilson, W. C. Belcher, A. B. Dibble and James R. Byrne as their attorneys.

And on the 26th day of July, 1878, the court proceeded to hear the testimony offered on behalf of the plaintiff and defendants, the hearing of which occupied until and including the 9th day of August, 1878.

On the 17th day of February, 1879, the cause was argued by the respective attorneys and submitted to the court for decision, and now the court having duly considered the said above evidence and the arguments of counsel and deliberated thereupon, now files its findings of fact and conclusions of law as follows:

Findings of Fact.

I. The plaintiff is the owuer and in the possession of 1,069 acres of land situated in Sutter county, State of California, in township B (13) north, range 14 east, Mount Diablo base and meridian, lying upon and along the southerly bank of Bear river and about 10 miles below where that river leaves its canyon and enters the valley and about the same distance from the mouth of said river.

The whole of said land originally belonged to the United States, and the United States title in the different parcels became vested in the plaintiff at various times, as follows: June 13th, 1866, being lots 1 and 3 of section (11) 11; June 15th, 1866, being the northwest quarter of section 13, the S. E. one-fourth of the S. E. one-fourth of section 11, and south half of the southwest quarter, and the northeast quarter of the southwest quarter of section 12, and the uortheast quarter and southeast quarter ot section 14.

On the 10th day of September, 1866, the S. W. quarter of section 13; June 1st, 1872, lots 3, 4 and 5, of section 12; June 1st, 1874, the west half of the west half of section 14.

December 11, 1875, those parcels aggregated 1,069 acres. The title to the following parcels of the foregoing lands was conveyed by the United States to the grantors of the plaintiff at the following periods of time, viz.: April 30, 1862, the NE. ¼ of the SW. ¼, and the S. ½ of SW. ¼ of section 12; the E. ½ of section 14; the SE. ¼ of the SW. ¼ of section 11; containing 479 55-100 acres. January 4, 1866, the NW. ¼ of section 13, containing 160 acres. June 1, 1872, the SW. ¼ of section 12, containing 69 39-100 acres. September 6, 1872, the W. ½ of W. ½ of section 14, containing 154 26-100 acres.

Upon these lands between 1862 and 1871 the plaintiff placed lasting and valuable improvements, costing more than $10,000, and consisting of a large dwelling house, two barns, outhouses, orchard and a number of miles of fence, and *the like*, all of which improvements were on said land of the plaintiff at the time of its overflow with mining debris or tailings in the year 1875 and 1876, hereinafter described.

The said lands of plaintiff in their original condition were highly productive alluvial lands, adapted to the raising of wheat, corn and all the valuable agricultural products of the State.

That on the 15th day of January, 1875, 400 acres of plaintiff's lands were overflowed with the tailings or debris from the defendants' mines to a depth varying from three inches to three feet, and in March, 1876, from the same cause substantially, the same part of plaintiff's lands was again covered with another deposit of mining debris from defendants' mines.

The lands so overflowed are bounded by a line commencing at the center of section 13, and thence running north to the northeast corner of the NW. ¼ of the section; thence running nearly northwest across the SE. ¼ of the SW. ¼ of section 12, and continuing on a westerly course to old Bear river, and following it to the north line of section 14, at the center thereof; thence south on the center line of section 14 to the south line thereof; thence east to southeast corner of section 14; and thence to the center of section 13 to the point of beginning.

The dwelling house, outhouses and barns of the plaintiff were situated on the NW. ¼ of section 13, and also part of plaintiff's orchard.

The mining debris referred to consists of fine and coarse sand, small stone and sticky compound, composed of clay and sand, called slickens.

The effect of such overflows and deposits were to render the land overflowed and unproductive and incapable of any kind of cultivation during the year of the overflow and the year succeeding, and to permanently injure and largely impair the value of the land so overflowed, and to largely reduce its producing capacity, and to make it necessary for plaintiff to raise his dwelling house and outhouses and barns, which were situated on said overflowed lands, so as to make them habitable and fit for use, to likewise raise his fences and to expend large sums of money in repairing old and constructing new levees in and about which and for the productiou of his said lands, he has expended over $20,000.

That the deposits of the mining debris on plaintiff's land in 1875 and 1876 were an obstruction to the free use of that property and interfered with its use and enjoyments and very largely impaired its value iu the market as well its producing capacity.

That these deposits of mining debris upon plaintiff's land in January, 1875, and March, 1876, were part of the mining tailings deposited by the defendants in Bear river and its tributaries, and which by the waters of that stream and the water used by the defendants in their mining operations had been swept down Bear river upon the lands of the plaintiff.

That a continuance by defendants of their manner of using the bed of Bear river and its tributaries as a place for the deposit of their mining tailings will prevent the cultivation and utterly destroy all of plaintiff's land and render it unfit for agricultural uses or as a place of habitation.

That the defendants during the time they work their mines render the water of Bear river, opposite plaintiff's land, totally unfit for domestic or animal use or for the purpose of irrigation.

II. The defendants are the owuers of mining claims, which, three years before the commencement of this suit, and ever since they have worked by what is called the hydraulic process of mining.

These mining claims are situated at an elevation of 3,000 feet or thereabouts, above the level of the sea; about 60 miles from plaintiff's lands, and upon the hilltops adjacent to Bear river and its tributaries, and all lie within a radius of seven miles. These mining claims in the aggregate, include several thousand acres; one above containing 1,110 acres; the average depth to which these claims mined exceeds 50 feet; the upper part of these claims consists of free surface earth, the greater part of which was washed away into Bear river prior to 1862.

This earth is but slightly charged with gold, and does not pay for washing; below it is the channel of an old and extinct river—having a course at nearly right angles with the present rivers on the western slope of the Sierra Nevada.

Among the earth, stones and gravel, of this old river bed is found gold in greater quantities than in the superincumbent earth.

The mining claims of defendants are worked by means of immense blasts of powder to loosen or shatter the earthy matter, enormous heads of water to sweep the loosened matter into ditches, flumes and tail races set a heavy grade through which, at a great velocity, the earth, stones and water rush—the gold therein being separated from the earth by the action of the water and caught by means of pavements of stones and blocks of wood, set in the bottom of the ditches, flumes, tail races aforesaid, and the refuse matter known as tailings, and consisting of muddy water, sand, clay, coarse gravel, rounded quartz, pebbls and cobble stones, are deposited at the dump of these mining claims which are either in ths bed of Bear river or its tributaries, or in the beds of the steep ravines and gulches immediately contiguous to and leading into the bed of Bear river or its tributaries.

Unequal deposits are made from the several mining claims of defendants, depending upon the quantity and pressure of the water used by them, and the hardness or softness of the material at the time being worked.

These claims are worked from five to six months in the year; starting up about the 1st of January and continuing as long as the water lasts.

The deposits of the tailings from the mining claims of the defendants and at their dumps during the three years next preceding the commencement of this suit, was nearly 20,000,000 of cubic yards of tailings, and the annual deposit has been in that ratio, and is rapidly and annually increasing.

The mining claims of defendants are now only worked out to one-quarter their extent.

The number of men who receive employment from the mining claims of defendants is between 400 and 500.

The mines of defendants are the only ones shown by the testimony to have been in operation at the head of Bear river at the commencement of this suit, or during the three years before the commencement of this suit.

Bear river is a living stream, heading in or near the summit of the Sierra Nevada mountains, and pursues through deep defiles a westerly course until it touches the eastern margin of the Sacramento valley at a place called, "Camp Far West," where it debouches into that valley and crosses it on really the same course in a valley of its own, and empties into Feather river, at the town of Nicolaus, in Sutter county.

The altitude of Bear river valley at plaintiff's farm is about 70 (70) feet above the sea level. Its lands were originally agricultural lands of the first class, through which Bear river ran; is a well defined channel between high banks. The water thereof was clear in summer, and sufficiently pure at all seasons of the year for domestic or animal uses, or for purposes of irrigation.

The grade of Bear river and its tributaries from the dumps of defendants' mining claims to where it debouches into the Sacramento river is not less than 50 feet per mile, and where it runs through that valley, less than 10 feet per mile. The tailings deposited from the mining claims of defendants with the exceptions of the heaviest cobble, sand and other heavier stones, are swept by the force of the water in Bear river and its tributaries, and the water used by defendants in their mining operations down into Bear river proper, whence they become intermixed and by the same forces are swept down and through the defiles or canyons of Bear river, except the cobbles and other heavier stones, to the place whers said river debouches into the Sacramento valley.

That from the mouth of the canyon to the mouth of Bear river the grade of this stream is much reduced; that a large part of the slickings, sand and small stones from the defendants mines instead of passing through the channel of that river into Feather river, choked and filled its channel and overflowed its banks and adjacent lands with mining debris and caused it to form new channels in the valley which in time were closed and filled up with mining debris and new channels were thereupon formed at random in the valley, and from such causes a number of thousands of acres of rich and valuable agricultural land in Bear river valley have been covered to a depth varying from 18 inches to 15 feet with this mining debris consisting of sand, stone and slickings to the substantial ruin of such land

The water when first used by defendants mines is clear, but in being used for hydraulic mining, gains in solution, about five per cent. of its volume in earthy matter, and carries that percentage currently with the current down Bear river as far as plaintiff's lands. Water taken from Bear river opposite plaintiff's lands in January, 1875, contained nearly 30% of earthy matter. The travel of the heavier sand not held in solution by water, is about eight miles per day, while cobble stones from defendants' mines are forced by the water down Bear river, but at a slow rate. That since 1873 there has been a sensible and steady increase in the quantity of mining debris or tailings coming down Bear river into the valley from the mines of defendants, and this increase will steadily continue for years to come.

The deposits of mining debris at the head of the river have increased the grade, the bed of the stream, and smothered its bottom, and a smaller quantity of water brings down a greater amount of mining tailings than before such changes in bed of the stream occurred, that at least 40,000 acres of valuable and productive agricultural land in the valley of Bear river and the Sacramento proper eventually will be covered to the depth of several feet with mining tailings from the mines of defendants, and be rendered unproductive and uninhabitable if defendants continue to use the head of Bear river and its tributaries as a place of deposit for their mining tailings.

That within a short time after the hydraulic mines at the head of Bear river stop work, the water of Bear river becomes comparatively clear and fit for use, even after the early freshets of the winter, but before the hydraulic mines resume their operations.

That the mining operations at the head of Bear river before the year 1862 did no damage to the lands in the valley of Bear river, nor did they impair the quality of the water in that river so as to render it unfit for either of the uses known as domestic, animal or irrigating, and that to that time said lands and said water were not impaired or impured.

That the first damage to lands in the valley of Bear river from the mining debris occurred in the year 1862, which was a year noted for its extraordinary freshets.

During this year there was a heavy deposit of mining debris on about 200 acres of plaintiff's land, being the N. ½ of NE. ¼ of SW. ¼ of section 12; also, 20 or 30 acres in the NW. ¼ of SW. ¼ of the same section; lots 3, 4 and 5, being the fractional portions of section 12; also some lands in fractional portions of section 11.

These are different lands from those overflowed with mining debris in January, 1875, and March, 1876. No farther injury of consequence occurred to plaintiff's land from mining debris until January, 1875, and March, 1876.

That the year 1862 was the time of the commencement of hydraulic mining of considerable magnitude at the head of Bear river, and such business at that place has steadily increased in magnitude from that time to this. That there has been a similar increase each year (at the same stage of water) in the flow of tailings down Bear river and into the valley thereof.

That plaintiff never acquiesed in the wrongful acts of defendants and has not yet been guilty of laches of faults in not applying for relief sooner, as he and a large number of persons owning similarly situated land in the valley of Bear river, were endeavoring by constructing levees, new channels, drains, opening sloughs and straightening channels to protect their lands from being overflowed by mining debris, and believed that they could so protect themselves and were expecting a dimunition in the flow of tailings and that they would have succeeded in protecting their lands, but for the increase of the deposit of tailings in the bed of Bear river and its tributaries and the increase in the flow thereof into the valley of Bear river commencing in 1873, and gradually increasing and ending in the overflow of January, 1875, and March, 1876, of plaintiff's land as described in the first article of these findings; that at the commencement of this suit the waters of Bear river opposite plaintiff's land were, and are now, so foul and corrupted by the deposit of mining tailings therein from defendants mines, as to be unfit for use by man or animals or for the purposes of irrigation.

III. That each of the defendants has materially contributed to the injury and damage of plaintiff's land by washing into Bear river and its tributaries the tailings from their several mines, and intend to continue so to do.

That it is and will be impossible for plaintiff to ascertain or prove the proportion in which either or any of the said defendants have contributed to his damage and injury as aforesaid or will hereafter contribute to the damage and injury apprehended by him as aforesaid.

IV. That the defendants styled the Little York Gold Washing and Water Co., (limited) and the Cedar Creek Gold Mines and Water Co., (limited) and the Bird's-Eye Creek Gold, Silver and Copper Mining Co., (limited) are each foreign mining corporations, created under the laws of Great Britain, and that neither of them has at any time filed in the office of the Secretary of State of the State of California any paper designating or purporting to designate in behalf of their respective companies any person or persons whom process issued by authority of or under any law of this State may be served upon such company, or either of them, nor have they, or either of them, in any measure complied with or attempted to comply with any of the requirements of section of the Act entitled: An Act in relation to foreign corporations, approved April 1st, 1872.

V. That about the year of 1852, mining districts were formed which embrace all the mining claims of defendants, and mining laws were adopted, prescribing the size, mode and manner of locating and holding mining claims in such districts, and when such modes and regulations were not regularly adopted those matters were controlled by the customs prevailing in such district or districts. No law, custom or usage regulated or purported to regulate the manner in which mining claims should be worked. Locations of mining claims were made in accordance with the laws thus adopted; water for mining purposes were appropriated; ditches constructed and many operations requiring the use of water were commenced. The operations have been carried on with some intermissions and changes in the mode of working.

Continuously up to the present time since the commencement of gold washing in California to the present time, miners have discharged the tailings coming from mines into the nearest or most convenient ravine or outlets, and such has been the practice in all the mining districts of the State.

That from 1856 up to the present time the defendants and those through they claim, and all others engaged in mining within the water shed of Bear river have openly, continuously and notoriously washed, worked and mined their claims by the use of water as a power, and dumped and discharged the tailings from their mines into said Bear river and its tributaries, streams, canyons and ravines, as was most convenient and practicable.

The mining claims of D. W. Balch, substituted as defendant in the place of the Little York Mining Co. (limited), were located not later than the year 1874.

The defendant Balch has been the owner thereof since March 8th, 1876; his grantor, the Little York Co. (limited), has been the owner since October 3d, 1873; his grantor received a patent from the United States, dated June 10th, 1872.

The dumps or discharge grounds of said mining claims is upon ground embraced within the limits of said patent; Balch paid $100,000 for these claims and their estimated value exceeds that sum. The mining claims of the Cedar Creek Gold Mines and Water Co. (limited), were located between 1852 and 1861.

This company acquired its title to said claims in 1872; United States patent for these claims were issued to it in the years 1873 and 1875. The dumps or discharge of said claims is upon grounds embraced in said patents, said mining claims, including their water rights, cost $475,000, which is their estimated value.

The mining claims of the defendant, the Bird's-Eye Creek Gold Mining Co., were located in the year 1852; its title accrued on the 30th day of March, 1871. Such claims were patented to it by the United States on the 8th day of April, 1874.

The dump or place of discharge of two of its claims is upon ground embraced within the limits of said patent, to wit: The Neece & West, and Wallowps claims.

The claims cost the present owner $380,000. Their greatest value is estimated at $500,000.

The mining claims of the Franklin Mining Co. was located in the year 1874. This defendant has been the owner of such claims since January 21st, 1875; its title comes through a patent from the United States, dated June 22d, 1872.

The mining claims of the Polar Star Hydraulic Gold Mining Co. were located in the years 1852 and 1874. This company has been the owner of said claims since October 13th, 1875. It holds its title to said claims under a patent from the United States, dated June 22d, 1872. The dumps or discharges of said claims is upon ground embraced within the lines of said patent.

The mining claims of the defendants, the Oold Run Ditch and Mining Co., were located prior to the year 1867. This company acquiried its title May 31st, 1872. There has been no work done on the claims of this company known as Pine Tops since March, 1874.

The mining claims of W. and P. Nichols, substituted as defendants in place of John, Charles, and James Staples, was located in the year 1855. Defendants Nichols has been the owner thereof since the 24th of April, 1878. Their grantors were owners from September 21st, 1874. Their patent from the United States is dated July, 1874.

The mining claims of the defendant, J. H. Le Kamp, were located in the year 1856. The defendant, Le Kamp, has been the owner of such claims since July, 1872.

The mining claims of the defendant, B. Huysink, were located prior to the year 1856. The defendant, B. Huysink, has been the owner of such claims since August 19th, 1872. He holds his title thereto by United States patent, dated June 22d, 1872. The dump or discharge of said claims is upon grounds embraced within the limits of said patent.

The mining claims of the defendant, W. H. Raymond, were located prior to the year 1860. The defendant, Raymond, has been the owner of such claims since November 22d, 1873.

The mining claims of the Camden Mining Co., substituted as defendant instead of Edward Carney and P. L. Goodseed, were located prior to the year 1856. The Camden Mining Co. have been the owner of such claims since the year 1856.

The mining claims of the defendants, A. A. Sargent and William Jacobs, the latter substituted instead of George F. Jacobs, were located prior to the year 1857. The defendant, A. A. Sargent, has been the owner of an undivided one-half interest in said claims since 1861. The defendant, William Jacobs, has been the owner of an undivided one-half interest therein since December 1st, 1877; his predecessor in interest, George F. Jacobs, has been the owner of an undivided one-half interest therein since 1857. Said defendants hold their title to said mines under a patent from the United States, dated June 4th, 1872. The dump or discharge of said claims is upon grounds embraced within the limits of said patent. Their estimated value is $250,000.

The defendant, John Hussey, has been the owner of the Hussey claim since October, 1874. Said claim was located in the year 1858. A United States patent was applied for in June, 1878, but such patent has not yet been issued.

The mining claims of defendants, Knight Bros., were located prior to the year 1859. They are worked by what is called the drifting process, which does not disturb what is called the upper strata, but drifts out and washes what is called the pay streak or lower strata. The tailings from these claims are deposited in the bed of a creek which leads into one of the main tributaries of Bear river.

The defendants, the Knight Bros., were located in the year 1859. The defendants, Wyck Bros., have been the owners of these claims since 1858.

These claims are partly worked by the hydraulic process and partly by the drifting process. The tailings from these claims are deposited in one of the tributaries of Bear river.

The mining claims of the defendants, Nutting, Cooper, Frick & Frick, were located prior to the year 1867.

The defendants have been the owners of these claims since the year 1867. In the year 1859 they applied to the United States for a patent and paid therefor, and have a certificate of purchase therefor. These claims are likewise worked by what is called the drifting process. Their tailings are deposited in a ravine which leads into one of the tributaries of Bear river.

The defendants, A. G. Turner, sued as H. E. Turner, never was the owner of or in any way interested in the mining claim called the Gouge Eye. He never worked upon or mined the same or discharged therefrom any tailings into the bed of Bear river or its tributaries.

The defendants, the Elmore Hill Hydraulic Mining Co., and the Chalk Mountain Blue Gravel Mining Co., although duly served with summons complaint herein, did not answer or defend their suit.

Hydraulic mining, in the sense by which that term is now generally understood, was introduced in the mining districts at the head of Bear river in a limited way as early as 1852.

The defendants, except those engaged in drift mining, have, in conducting the mining operations, followed what is called hydraulic mining, in the manner in which the same is described in the findings; and this method of mining is the most economical as well as the most effective method known of separating such gold in such mining claims, from the earth, stone, and gravel which contain it.

The dumps or places of discharge of the various mines of the defendants are not contiguous nor in close proximity to each other, with a few exceptions, but in all cases the tailings from the various mines commingle and run together in Bear river before they reach the land of the plaintiff. Said dumps are in many instances several miles apart from each other.

The gold contained in the gravel deposits on the Blue Lead, upon which the claims of defendants are situated, varies from $50,000 to $300,000 per acre, as estimated or conjectured.

The cessation of hydraulic mining would greatly reduce the taxable property of all the mining counties of the State.

VII. The cause of action of plaintiff and his right to the relief demanded by him is not barred by any or either of the statutes of limitations set up by either of the defendants in their answers herein.

Conclusions of Law.

1. That the plaintiff's cause of action and his right to the relief herein demanded is not barred by all or either of the statutes of limitation pleaded by the defendants in this case or otherwise.

2. The defendants or either of them have not acquired any right to use the bed of Bear river nor the beds of its tributaries as a place of deposit of their mining tailings, nor to choke and fill with such tailings the channels of Bear river in the valley thereof, nor to flow or overflow plaintiff's lands with such tailings, nor to corrupt, foul and make unfit for domestic, animal or irrigating uses, the water of Bear river.

3. The acts of defendants and each of them constitute a nuisance and are an obstruction to the free use by plaintiff of said lands and an interference with the comfortable enjoyments of said property by him.

4. The mining laws and mining customs of the several mining districts mentioned and referred to in the findings of fact herein were not intended to and did not and cannot protect the defendants in the doing of the acts, matters and things complained of in this action.

5. The plaintiff is entitled to the relief by him demanded. Let judgment be entered accordingly.

PHIL. W. KEYSER, District Judge.

Decree.

James H. Keyes vs. Little York Gold and Water Co. (limited), et al.

In the foregoing cause the defendant having duly appeared, and the case having been duly tried and argued, the Court, after due consideration thereof, doth order, adjudge and decree as follows, to wit: That D. W. Balch, substituted as a defendant herein instead of the Little York Gold Washing and Water Co. (limited); the Cedar Creek Gold Mines and Water Co (limited); the Bird's-Eye Creek Gold Mining Co. (limited); Franklin Gravel Mining Co.; Polar Star Hydraulic Gold Mining Co.; Elmore Hill Hydraulic Mining Co.; Chalk Mountain Blue Gravel Co.; Gold Run Ditch and Mining Co., substituted as a defendant instead of the Miners' Ditch Co.; W. and P. Nichols, substituted as defendants instead of John, Charles, and James Staples; also J. H. Le Kamp and B. Huysink, W. H. Raymond and John Hussey; Camden Mining Co., substituted as a defendant herein instead of Edward Carney and P. L. Goodspeed; L. W. Preble. A. A. Sargent, and William Jacobs, co-partners under the name of Sargent & Jacobs, the latter substituted as defendant instead of George F. Jacobs; also H. Knight and William Knight, co-partners under the name of Knight Bros.; Conrad Wyck and P. Wyck, A. N. Nutting, Alonzo Cooper, J. B. Frick, and O. A. Frick, substituted for defendants impleaded as Nutting, Cooper, Frick and Frick; and the Superintendents, agents, officers, servants and employees of the foregoing defendants, and each of them be, and they are each of them hereby perpetually enjoined and restrained from using the bed of Bear river, or the beds of any or either of its tributaries, ravines or gulches, as a place of deposit, or as a dump or place of discharge for the tailings or debris of their said mines or mining claims or either of them, and especially from using said beds of said stream or either of them as a place of deposit of the tailings from those mining claims known as the Empire, Christmas Hill, Council Hill, Liberty Hill, Yankee Badger, Jehosaphat, Central Red Dog, Wallapa, Neece & West, Franklin, Polar Star, Buckeye, American, Elmore Hill, Chalk Bluff, Pine Tops, Somerset, Le Kamp, North Star, Sailor, Boston, Doolittle, Hussey, Gouge Eye, Quaker Hill, Rhode Island, Remington Hill, Wyck Bros'. claim, Lowell Hill, Swamp Angel, Pleasant or Mount Pleasant, and especially from continuing to use their present dumps as a place for the discharge and deposit of the tailings or debris from said mines; and they and each of said defendants are further hereby perpetually restrained and prohibited from fouling and corrupting the water of Bear river, and its branches, tributaries, streams, ravines and gulches, with tailings or debris from their said mines, or either of them; that the plaintiff herein recover his costs of this suit taxed at $—— against the foregoing named defendants, except the Oold Run Ditch and Mining Co.; that the defendant, A. G. Turner, having disclaimed the complaint of plaintiff as to him, is hereby dismissed, but without cost to either party.

Done at Chambers, this 10th day of March, A. D., 1879.

PHIL. W. KEYSER, District Judge.

INDIAN LANDS.—Of the forty-one million acres of land in the Indian Territory, twenty-six millions have been set apart for savages and the remaining fifteen millions are unsurveyed and belong to the United States. The Indians who have thus far gone there have done practically nothing in the way of developing the immense resources there to be found. If the land was equally divided up among these Indian emigrants, it would average over 500 acres to each, which in the hands of industrious white settlers might have been made to confer immense benefits upon the country in the way of opening up one of the richest and most magnificent districts to be found between the Atlantic and Pacific. The soil, climate, water facilities and all other natural characteristics are the best and most desirable to be found anywhere in the country. No civilized government has ever been organized there—the Indians having it all to themselves and doing nothing with it.—*Arizona Enterprise.*

HAYSTACK FIRES—WASP INCENDIARIES.—The frequent mysterious burning of haystacks and farmers' buildings has led to the discovery that they are usually set on fire by wasps' nests, and that the nests are ignited by spontaneous combustion. This is produced by the chemical action of the wax in contact with the paper-like substance of which the nest is composed, a comparatively small access of oxygen being sufficient to make it burst forth in a blaze.

An Eastern View of Pacific Coast Timber Preservation.

Prof. C. S. Sargent, Director of the Botanic Garden of Harvard University, writes an article on forestry for the *Nation*, in the course of which he presents his views on the destruction of timber on this coast and the means of restoring depleted forests. He thinks at the East the restoration may be left to individual and corporate intelligence and enterprises, and then continues as follows:

West of the Rocky mountains all is different. The country is cut up by high mountain chains overlooking narrow valleys. The rainfall is in parts of this region exceedingly small, and everywhere very unequally distributed throughout the year; so that once destroyed it would be difficult or, indeed, impossible to restore any forests of this region beyond the immediate influence of the Pacific ocean; while its peculiar topography demands that the mountain ranges remain forest-covered that the valleys may be habitable. Large portions of this Western territory are still in the hands of the general Government, and before it is too late, steps should be taken to set aside and scrupulously preserve at least such portions of forest-covered mountain ranges as give rise to important streams. It is probably already too late to preserve any considerable part of the scanty forests of the "Great basin." They are everywhere fast melting away to supply the enormous and often unnecessary demands of the mining enterprises of that region. These forests, which are of immense age, once destroyed, will never reappear, and the streams which now make agriculture possible in the valleys through irrigation will, at no distant day, flow only during a short period of the year. If any portion of this interior region is worth saving for agriculture, immediate steps must be taken to preserve the remnants of its forests, or it will not long support even its present small agricultural population.

More important still is the necessity for Government or State preservation of some part of the noble coniferous forest which graces the western slopes of the Sierra Nevada. The future of California depends on the existence of this forest. Nowhere on the face of the globe is the physical necessity for preserving the forests greater than in California; nowhere has the world seen its forests so rapidly and senselessly destroyed. We will briefly examine what the dangers are which threaten California, and what should be undertaken to prevent or at least diminish them. All along the western slope of the Sierras numerous rivers head, which, flowing westward through the rich foothills and great plains of California, fall into the Sacramento and the San Joaquin, the one flowing south and the other north, and at length emptying into the bay of San Francisco. Through these rivers must pass all the moisture, not absorbed by the soil, which the Sierras attract from the ocean lying almost at their feet. The annual precipitation of moisture in these mountains, although almost exclusively confined to the winter months, is still very large, a fall of 60 feet of snow during an exceptionally severe winter having been reported in the high Sierras. It results that in the early summer months, when the snow is melting, these mountain streams become large and rapid rivers, carrying off immense volumes of water, and then almost entirely disappearing with the snow. As they are not replenished by summer rains, the length of their annual duration must depend on the slowness with which the snow at their sources melts. It is a well-known fact that snow melts much less rapidly, and that much more of it is absorbed in the forest than in the open ground; while the forests on a mountain side offers great mechanical resistance, especially by their undergrowth and coating of fallen leaves, to the rapid running off of water or melting snow. If the forests of the Sierras are destroyed, their annual snowfall will probably not be materially diminished. The length of time, however, required to melt it will be much shorter; and the absorbing power of the forest being gone, the volume of water passing through the rivers will be greatly increased. It is not difficult to foretell the results. Every season, earlier at the south, later at the north, torrents, more terrible and more destructive than the history of the world records, will carry during a few weeks death and desolation from the mountain-sides down over the footbills, covering the plains with debris and holding the cities lying along the low banks of the larger rivers at their mercy. And then, when this terrible rush of a few days is over, it will be found that the whole supply of water for the summer is exhausted. The foothills and the plain will no longer produce fruits or vegetables, or any summer crop for which irrigation is essential, for no water to irrigate with will come down from the mountains. "Placer mining" will be a thing of the past, and even the navigation of the great rivers will be either interrupted or abandoned. During the last 50 years more than one country in Europe has been visited by calamities similar in origin and extent to those which now threaten California, but in none of them were the physical reasons for the danger so great. The mountains from which the destructive torrents of Europe have sprung are lower than the Sierras, less heavily forest-clad, and enjoying a more regular precipitation of moisture with a much smaller snowfall, and so less able to produce sudden and disastrous torrents.

There is but one remedy for the dangers we foretell, and on its adoption depends the future of California. A strip or strips of forest must be set aside along the western slope of the Sierras extensive enough to secure the natural flow of rivers, and these reservations must be strictly guarded from fire, the axe, and especially from all browsing animals. It is in her boasted millions of sheep that California's greatest danger now lies. These, with countless herds of other browsing animals, are driven up every summer from the plains into the mountains to feed during the dry season. The damage they are inflicting in the Sierra forests is terrible and indescribable. One can ride for days at a certain elevation through the mountains along the sheep-trails without seeing outside of the rare ranch enclosures a single uninjured shrub or a seedling tree of any sort. Everything the sheep can reach is eaten clean. This means that there is nothing left of the forest but its older trees, and that it has lost or is fast losing its best element for holding back melted snow; and it means, too, that there are no new trees coming on to take the place in their turn of their parents. As the number of animals driven to the mountains increases, forest fires increase also, set by the shepherds either accidentally or purposely to increase the next year's feed. A forest annually wasted by fire, on which the axe is always making terrible inroads, and in which no young trees are allowed to spring up, is clearly doomed. When that of the Sierras, the noblest of our continent, has gone, nothing will stand between California and the dangers which threaten her. To preserve California is the first and greatest duty of American forestry. The task is a difficult one, but it can be accomplished if her people desire it.

Useful Information.

Facts of Value to the Housewife.

That salt will curdle new milk; hence, in preparing milk-porridge, gravies, etc., the salt should not be added until the dish is prepared.

That fresh meat, after beginning to sour, will sweeten if placed out of doors in the cool air overnight.

That clear, boiling water will remove tea stains and many fruit stains. Pour the water through the stain, and thus prevent it from spreading over the fabric.

That ripe tomatoes will remove ink and other stains from white cloth, also from the hands.

That a tablespoonful of turpentine boiled with your white clothes will greatly aid the whitening process.

That boiled starch is much improved by the addition of a little sperm, or a little salt, or both, or a little gum arabic dissolved.

That beeswax and salt will make your rusty flat-irons as clean and smooth as glass. Tie a lump of wax in a rag, and keep it for the purpose. When the irons are hot, rub them first with the wax rag, then scour with a paper or cloth sprinkled with salt.

That blue ointment and kerosene mixed in equal proportions and applied to bedsteads is an unfailing bedbug remedy, and that a coat of whitewash is ditto for the walls of a log-house.

That kerosene oil will soften boots or shoes which have been hardened by water, and render them as pliable as new.

That kerosene will make your tin kettle as bright as new. Saturate a woolen rag and rub with it. It will also remove stains from, and clean, varnished furniture.

That cold rain-water and soap will remove machine grease from washable fabrics.

Japanese Magic Mirrors.—The so-called magic mirrors, with which the Japanese metal-workers have hitherto succeeded in puzzling our *savants*, have been generally supposed to owe their strange property of reflecting images that were quite invisible upon their brilliantly polished surfaces, to corresponding inequalities in the density of the surface, produced by some means during cooling or by stamping. Professors Ayrton and Petty, who have lately studied their peculiarities, offer another explanation. They affirm that the effects above noticed are produced by reason of very slight irregularities in curvature of the polished surfaces, these irregularities being such that the thicker parts, corresponding with the raised patterns on the back, are flatter than the remaining convex surface, by which difference there would be less dispersion of light from the thick than from the thin portions of the surface. As, unless we are greatly mistaken, we remember to have seen such mirrors with apparently perfectly plane surfaces, the above explanation would appear to be less satisfactory than the older one.

Case-Hardening Iron.—In order to economize in the more expensive materials for case-hardening cast, wrought or malleable iron, and to harden only portions of the article in different degrees, if required, Mr. Gracie S. Roberts, of Brooklyn, makes use of an improved method. After polishing the surface, he glues to the portions to be case-hardened a coating of yellow prussiate of potash. A number of coats are given, according to the degree of the case-hardening required. A cheaper material or simply boneblack is used where a slight effect only is required. When the glue is set hard, the article is packed in powdered charcoal, heated to redness in a quick fire and maintained at that heat for half an hour. Then it is hardened and tempered in the usual manner.

Coating Metals With Tin.—The process of coating metals with tin promises to extend its use for culinary and other uses. Its electro-deposition is proposed by means of a zinc and carbon battery. The inner cell containing the zinc is filled with dilute sulphuric acid. The articles to be coated with tin are put into a bath composed of 8 parts of protochloride of tin, 16 of cream of tartar, and 2 of the chloride if the latter is used. When it is present the tin coating is effected more rapidly, whereas, when the bath is composed of protochloride of tin and cream of tartar only, the tin coating is very white, but is not produced so rapidly as when the chloride is used. These ingredients should be dissolved in about 100 gallons of distilled water. The black plates are first "pickled" in any suitable manner, and then immersed in the above described bath or solution, and are allowed to remain in the same for a longer or shorter time, according to the thickness of the deposit or coating of tin required on the plates. While in this bath the plates or other pieces to be coated are connected by a wire with the positive end of the battery, while the negative end of the battery is connected with a piece of tin hung in the same bath. When the plates or other pieces or articles have been sufficiently coated with tin, they are held over a fire in order to give the tin a lustrous appearance.

Triumph of Electrical Science.—In the cable news of a few days since, it was stated that the French Atlantic cable was "broken 161 miles from St. Pierre Miquelou, in 500 fathoms of water." These few words show one of the many triumphs of modern electrical science. Here is a wire cord buried under three-fifths of a mile of the water of the ocean, and 160 miles from land—and yet the people on shore can exactly locate the points at which it is broken. Strange as that seems, it is actually done, and has been time and again. The repairing vessels will go out to the indicated point, throw over their grappling hooks, and within a few hundred yards will find the broken ends and splice them. This wonder is accomplished, first, by exact knowledge of the laws of electricity, which make known what amount of currents a wire of a given dimension will carry, and the resistance it must overcome in going to a given distance, and, next, by the instruments made by the mechanicians of our day, which will make the operation of both laws visible to the experienced observer, even if the break in the cable is a thousand miles away and two miles under the sea.—*Philadelphia Ledger.*

To Make Iron Take a Bright Polish like Steel.—Pulverize and dissolve the following articles in one quart of hot water: Blue vitriol, one ounce; borax, one ounce; prussiate of potash, one ounce; charcoal, one ounce; salt, one half-pint; then add one gallon linseed oil. Mix well, bring your iron or steel to the proper heat and cool in the solution. It is said the manufacturers of the Judson governor paid $100 for this recipe, the object being to case-harden iron so that it would take a bright polish like steel.

The Locomotive.—The ordinary life of a locomotive engine is stated at 30 years. Some of the small parts require renewal every six months. The boiler tubes last five years, and the crank axles six years; tires, boilers and fire-boxes six to seven years. The side frames, axles and other parts 30 years.

Good Health.

What to Do in Cases of Diphtheria.

[From the Circular of the Massachusetts State Board of Health.]

In the first place, as diphtheria is a contagious disease, and under certain circumstances not entirely known, very highly so, it is important that all practical means should be taken to separate the sick from the well. As it is also infectious, woolen clothes, carpets, curtains, bangings, etc., should be avoided in the sick room, and only such materials used as can be readily washed.

All clothes, when removed from the patient, should be at once placed in hot water. Pocket-handkerchiefs should be laid aside, and in their stead soft pieces of linen or cotton cloth should be used, and at once burned.

Disinfectants should always be placed in the vessel containing the expectoration, and may be used somewhat freely in the sick room; those being especially useful which destroy bad odors without causing others (nitrate of lead, chloride of zinc, etc.) In schools there should be especial supervision, as the disease is often so mild in its early stages as not to attract common attention; and no child should be allowed to attend school from an infected house, until allowed to do so by a competent physician. In the case of young children, all reasonable care should be taken to prevent undue exposure to the cold.

Pure water for drinking should be used, avoiding contaminated sources of supply; ventilation should be insisted on, and local drainage must be carefully attended to. Privies and cesspools, where they exist, should be frequently emptied and disinfected; slop water should not be allowed to soak into the surface of the ground near dwelling-houses, and the cellars should be kept dry and sweet.

In all cases of diphtheria fully as great care should be taken in disinfecting the sick room, after use, as in scarlet fever. After a death from diphtheria, the clothing disused should be burned, or exposed to nearly or quite a heat of boiling water. The body should be placed as early as practicable in the coffin, with disinfectants, and the coffin should be tightly closed. Children, at least, and better adults also in most cases, should not attend a funeral from a house in which a death from diphtheria has occurred. But with suitable precautions, it is not necessary that the funeral should be private, provided the corpse be not in any way exposed.

Although it is not at present possible to remove at once all sources of epidemic disease, yet the frequent visitation of such disease, and especially its continued prevalence, may be taken as sufficient evidence of insanitary surroundings, and of sources of sickness to a certain extent preventable.

It should be distinctly understood that no amount of artificial "disinfection" can ever take the place of pure air, good water and proper drainage, which cannot be gained without prompt and efficient removal of all filth, whether from slaughter houses, etc., public buildings, crowded tenements or private residences.

Temperature of the Head.—Some investigations have recently been made by several physiologists concerning the effect of mental activity upon the temperature of the brain. Several thermometers are placed on different parts of the head and fastened there by means of straps; then the person subjects himself to various intellectual processes, and the result shows a decided increase of temperature in certain parts of the brain. The temperature of the brain of a professor was elevated several degrees while delivering a lecture. Even the slightest intellectual effort raises the temperature of the head above that which it reaches in idle conversation. It is interesting to note that certain parts of the brain show a greater increase of temperature than others. Where the temperature of the head is increased beyond a certain point, intellectual effort takes place with difficulty, or with pain. This is very apt to be the case with persons of a very nervous temperament. It would therefore be prudent for such to cease intellectual effort, before the temperature is reached, and devote themselves to some physical exercise which shall equalize the circulation and restore the normal temperature to the extremities.

Morning Walks not Healthful.—It is a great mistake, says a medical writer, to suppose that a morning walk or other form of exercise before breakfast is healthful; the malaria which rests on the earth about sunrise in summer, when taken into the lungs and stomach, which are equally debilitated with other portions of the body from the long fast since supper, is very readily absorbed and enters the circulation within an hour or two, poisoning the blood, and laying the foundation for troublesome diseases; while in winter the same debilitated condition of these vital organs readily allows the blood to be chilled, and thus renders the system susceptible of taking cold, with all its varied and too often disastrous results. Some will say, look how healthy the farmer's boy is, and the daily laborers, who go to their work from one year's end to another by "crack of dawn!" My reply is, if they are healthy, they are so in spite of these exposures; their simple fare, their regular lives and their out-door industry, give their bodies a tone, a vigor, a capability of resisting disease, which nullifies the action of malaria to a very considerable extent.

Dangerous Houses.—Houses that have been empty may become fever breeders when they come to be reoccupied. An English sanitary officer alleges that he has observed typhoid, diphtheria, or other zymotic affections to rise under these circumstances. The cause is supposed to be in the disuse of cisterns, pipes and drains, the processes of putrefaction going on in the impure air in them, the unobstructed access of this air to the house, while the closure of windows and doors effectually shuts out fresh air. Persons moving from the city to their country homes for the summer, should see that the drains and pipes are in perfect order, that the cellar and closets are free from rubbish, and the whole house thoroughly aired before occupying. Carbolic acid used freely in the cellar is a cheap and good disinfectant.

The Treatment of Sprains. Mr. Dacre Fox, an English surgeon to a large railway company, who has had considerable experience of this form of injury, says that in the more severe cases he finds that after a few days of fomentation the best treatment is regulated pressure by means of carefully adjusted pads and large plasters of a special shape, varying according to the particular joint involved. By this plan he feels sure that it is possible to control the effusion into the sheaths of the tendons and adjacent structures, to lessen the pain, and to shorten the duration of treatment.

Treatment of Diphtheria.—Dr. Bachelder, in an Australian journal, says: "I would suggest to physicians, in treating diphtheria, to use internally a very weak solution of carbolic acid, and for the throat or fauces a solution of hydrochloric acid, about the strength of strong cider vinegar. I have treated every case successfully, so far, with the above remedies. Croup is instantly relieved by the acid solution. Apply it to the throat with a brush or sponge, or use as a gargle."

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Quicksilver Combination; Combination Lathes; The Proposed Free Library, 177. The Week; Relative Increase of Gold and Silver; A Sub-Aqueous Excavator; The Perils of Stock Speculations, 184. Arizona.—No. 1; Boiler Explosions.—No. 3; The Sutro Compromise; Russell's Cultivator, 185.
ILLUSTRATIONS.—Combination Lathe, 177. P. S. Russell's Improved Cultivator, 185.
CORRESPONDENCE. — Nevada's Wealth, 178.
THE ENGINEER.—Cheap Railways; Wire Belts, 178.
MECHANICAL PROGRESS.—Welding of Metals at Low Temperatures; Motive Power from the Condensation of Steam; Old and New Objects of Invention; Shipbuilding in the United States; Working up Iron and Steel Shearings; Paper vs. Iron Car Wheels; Artificial Marble Produced by Steam Heat and Pressure, 179.
SCIENTIFIC PROGRESS — The Telectroscope; Something curious about Explosives; Powders Solidified by Pressure; Potassium; Geological Changes in Progress; New Instrument to Determine the Presence of Metals in Ores; The New Metals; A Rare Mineral, 179.
MINING STOCK MARKET — Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 180.
USEFUL INFORMATION.—Facts of Value to the Housewife; Japanese Magic Mirrors; Case-Hardening Iron; Coating Metals with Tin; Triumph of Electrical Science; To make Iron take a Bright Polish like Steel; The Locomotive, 183.
GOOD HEALTH.—What to do in Cases of Diphtheria; Temperature of the Head; Morning Walks not Healthful; Dangerous Houses; The Treatment of Sprains; Treatment of Diphtheria, 183.
MISCELLANEOUS.—The Mining Debris Question; Indian Lands; Haystack Fires—Wasp Incendiaries, 182. An Eastern View of Pacific Coast Timber Preservation, 183.
MINING SUMMARY from the various counties of California, Nevada, Idaho and Colorado, 181-88.

The Week.

Better times are coming. The Eastern journals—especially in New England—speak in encouraging terms of the indications about them of the improvement in business, and the late plentiful rains here, have assured us of such bountiful harvest, that the turn in the tide of business affairs seems evident, though necessarily slow in making itself manifest. In other countries the dull times and attending distress continue unabated. Wages have been generally lowered throughout England, and large numbers of the laboring classes thereby rendered destitute. Colonization seems to have been decided upon as a remedy for these troubles. Several schemes have been projected in England, Ireland, Germany and France, to settle colonists in America, and Italy has a large band of immigrants en route for New Guinea. After months of patient talk and negotiations the Sutro Tunnel Co. and the Comstock mines have at last effected a compromise. This is good news to all concerned, for not only is it a benefit to the mine owners themselves, but to the miners also, hundreds of whom are now out of work at Virginia. The land contest between the Railroad company and the settlers of Tulare county is assuming a rather threatening aspect. The latter have organized six military companies under the State laws, and declare their intention to resist all attempts to deprive them of their homes. The action of the government concerning Alaska seems peculiar. Sitka is only protected by the presence of a British man-of-war, and yet the government seems in no hurry to send an efficient force thither to protect its citizens, though the necessary means —the man-of-war *Alaska*—is on hand in this harbor waiting for orders, which up to Thursday morning had not been received.

Relative Increase of Gold and Silver.

There is a class of public journals in both the United States and Europe that, during the discussion in regard to the status silver should occupy in our national currency, held to the view that this metal was increasing the world over much faster relatively than gold, for which reason they expressed the opinion that it should suffer partial demonetization, at least, some of these journals being purely monometallic in their notions. And now comes to hand an English paper largely devoted to the consideration of financial economies and kindred topics, wherein this view is reiterated, and the fear expressed that much inconvenience and possibly loss will ensue from this threatened disturbance of the equilibrum that has heretofore existed between ths precious metals. As these are journals of wide influence, who's opinions with many will he accepted as authoritative, it may he well to examine this question a little and see if they have not fallen into an error.

During the three centuries preceding the discovery of gold in California, Mexico and South America heing then the principal bullion-producing countries of the world, the stock of silver was, no douht, heing replenished at a much more rapid rate than that of gold; the reason that the former did not accumulate to a troublesome or even marked extent, heing that India, which had meantime been opened to the trade of European nations, so absorbed this metal as to prevent such result. Since the discovery of gold in California, followed soon after hy like discoveries in Australia, the previously prevailing condition of things has been reversed, gold production having heen largely in excess of that of silver. Since 1848, when gold was first found on this coast, the value of all the bullion turned out in the countries lying west of the Missouri river, and mostly within the limits of the United States, amounts to a little over $2,000,000,000, of which $1,625,000,000 has been gold and only about $400,000,000 silver. That is, there have been added to the common stock of the precious metals during the past 30 years, four times as much gold as silver.

From 1849 up till 1862, when the Washoe silver mines began to make a notable yield, the disproportion was largely on ths side of gold. From 1862 the production of the two metals tended towards equalization, that of gold, which some years before had begun to fall off, continuing to decline while silver increased. This increase has not since been so great, however, as is generally supposed; first, because the so-called silver mines have themselves yielded a large percentage of gold; and secondly, because at ahout the time that the mines of California and Australia began to sharply contract their yield new sources of gold production were opened up, which went far toward counteracting the falling off that had occurred in these countries. In 1858 British Columbia began to contribute on the gold-increasing side of the question, followed successively during the next ten years hy Oregon, Idaho, Montana and Colorado, whose aggregate output has been largely on the same side.

Nevertheless, as before remarked, the general tendeucy has been towards equality, there having been but little difference between the value of the two precious metals produced on this coast for several years past. Last year the figures stood as follows: gold, $38,956,231; silver, $38,746,391. The preceding year the ratio was about the same, nor is it likely that we shall experience any wide departure from this rate for the present at least. There will unquestionably occur hereafter a large absolute increase of the precious metals throughout our Pacific States and Territories; the variations in the relative production, should any happen, heing in favor of gold. The bullion returns for California for 1878, as compared with the year before, show an increase of more than two millions in gold, and a decrease of nearly a million and a half in silver. In Montana the difference, though less, was the other way. In the other Pacific States and Territories there has during the past two or three years been but little change in this respect, Dakota having quite recently come in as a new gold factor.

While this equalizing process between the precious metals has so been in progress here, nothing of the kind has been going on in the other large bullion-creating countries of the world. In Australia no argentiferous deposits have been found or at least reported, while, for the past few years, there has been a slight increase in the gold gatherings of that country, partly through the discovery of new fields, and partly through a more general and successful working of the quartz reefs, of which they have great numbers and which must ultimately become a source of immense gold production. The Russian mines, in which country, too, the deposits are exclusively auriferous, turned out last year $23,250,000, it being generally understood that this industry is still quite in its infancy there, the methods and appliances employed in mining heing imperfect and vast regions remaining to be explored.

In Chile and various other States of South America there exists extensive deposits of auriferous gravel which, worked hy the hydraulic process, would no doubt prove highly prolific and profitable. Operations upon some of these deposits are about to be commenced, with every prospect that they will rapidly extend, and bringing enrichment to the owners, will through them add much to the common treasury. In the Transvaal (South Africa) gold mining employs a considerable population, and as they have extensive quartz reefs there also, the business promises to grow into a large, permanent and profitable industry. In Georgia, Virginia and the Carolinas gold mining, interrupted by the war, has lately been revived and is being extended at a rate that will insure for that section of the country no mean production in the course of a few years.

As in Australia, Siberia and Africa, so in the Southern States we hear nothing of silver lodes or silver mining, the only countries where this latter business seems likely to undergo early and marked enlargement being in Mexico and throughout certain States and Territories lying in and adjacent to the great interior basin, where also gold production will keep almost even pace with silver.

A Sub-aqueous Excavator.

At this time when the navigation of our rivers is being threatened with serious obstruction from the formation of sand bars and other depositions along them, anything that will enable us to remove these impediments in a cheap and effectual manner cannot fail to be regarded with general interest. In this view of the subject we append a brief description of a steam dredging boat, or sub-marine excavator, lately invented hy Dr. Thos. B. Carr, of Wilmington, N. C. This dredger is constructed and operates as follows: To the bow of a small stern-wheel steamer is affixed through bearings a strong upright iron bar, to the lower end of which is attached a double mold-board plow. The upper end of this bar forms a screw furnished with a wheel for raising and lowering it. To each wing of this plow is pivoted a bar running back and carrying a number of single mold-board plows, these bars being raised and lowered hy levers worked on the deck. By means of these levers and the screw bar at the bow, the entire gang of plows can be lifted and lowered as occasion may require. As the steamer advances this set of plows enters the sand bar or material to be removed, and stirring it up the sediment is loosened and swept away hy the current. Where the latter has not sufficient force to accomplish this, a centrifugal pump will be used, with which the material will be taken up and deposited into tank flats, or be discharged through troughs on each side of the boat, which will carry it off to a distance of 30 or 40 feet, making a channel from 60 to 80 feet wide. The machine, so far as tested, has been found to work well, and might perhaps do good service in helping to keep open navigation on the Sacramento and others rivers on this coast.

ARIZONA'S COPPER MINES.—The *Enterprise* in speaking of the very valuable deposits of this mineral, says: The copper mines of Arizona are rich and extensive, and with the advent of the railroad their worth will he appreciated, and capital invested in them will pay large dividends. These mines are found in every part of the Territory, and wherever they have been worked their richness has been made manifest. At Planet, in Yuma county, the mines have been worked ever since 1863, and work only shut down when copper suffered such a fall in price that they could not be made to pay the great cost of transportation and a handsome dividend besides. But with the advent of the railroad, transportation becomes easy, and copper ore, which without it would be worthless, now becomes of some value. At Clifton the mines have been made to pay well, although the ores had to be hauled hundreds of miles to the railway. In this county and Mohave county are many copper mines which show well, and, no doubt, before long they will be as much sought after and pay as large dividends as the richest of our gold and silver-hearing veins. We venture here to predict that before many years have passed Arizona will be the great copper-producing section of the United States.

NEW QUARTZ MILL.—A pair of the new Anderson ore stamps have recently been completed at the Pacific Iron Works, and are nearly ready to run, on the corner of Main and Harrison streets, in this city. This mill is a very ingeniously devised one of peculiar construction, made to run at very high speed. It is on an entirely different principle from any heretofore constructed, and looks as if it would do good work. As soon as the mill is running, we shall give a detailed description of its construction and operation.

THE Albany express recently ran over and killed a catamount which attempted to cross the track, between Jefferson and Marion stations, Oregon.

THE people of Pilot Rock, Umatilla county, Oregon, are building a fort 75x200 feet for the protection of families in case of an Indian war during the coming summer.

The Perils of Stock Speculation.

As a mining community we on this coast take a just pride in the rapid and effective manner in which we have developed our various forms of mineral wealth and made the improvements necessarily connected therewith. We have, to be sure, fallen into some mistakes; been a little wasteful and sometimes, too, a little over-sanguine, spending more money than we had counted upon and otherwise coming short of our calculations. But our record, as a whole, is one of which we may well feel proud. This is more especially true of what has been accomplished on the Comstock mineral range, where we have brought the business of vein mining and ore reduction to its greatest perfection, all that is best and most advanced in the mining industries of this coast finding there apt illustration. It is easy to find fault with the manner in which some things have been done even on the Comstock belt; it is easy for those who have had no practical connection with the working of these mines to criticise the men upon whom the onerous duties growing out of their management have been imposed. But it is doubtful if any set of men could or would have done the work any better. It was no ordinary task these men had to perform, and if sometimes they fell into minor errors these are not to he held up as evidence of incompetence nor commented upon in a censorious spirit.

But while the business management of the mines as well as their financial administration has been so generally unexceptionable, there has been a system of stock operations practiced in their names and ostensibly for their benefit, that will hear and even invites sharp criticism, and which, for the good of the large class who have suffered through the same as well as for the credit and true interests of the mines themselves; should meet with reproof and find early abatement.

In looking over the transactions of the San Francisco Stock Board for 1878, it will he noticed that the fluctuations in the prices of the leading Comstock shares have been sharp and frequent, these prices going up on occasions all at once from three to six, and even eight or nine hundred per cent., and then relapsing to former figures quite as suddenly, no corresponding change, and, in fact, no change whatever, having meantime occurred in the condition or prospects of the mines. In a few instances, as in the case of the Sierra Nevada, the Ophir, and two or three other mines perhaps, notable improvements have occurred, but even here the mining outlook has had but little to do with these rapidly advancing and receding prices, which have been brought about generally through extrinsic and foreign causes; having taken place not only in ths shares of mines that showed no change, but also in those that were not being worked at all.

These movements were, for the most part, based upon nothing substantial or tangible, having been effected through the machinery commonly employed for influencing the stock market; and yet they caused the prices of Comstock shares to fluctuate in the course of a single month to the extent of many millions. It is probable that an inventory of these shares might have been taken at several periods in the course of the year that would have showed a difference of from thirty to fifty million dollars in their aggregate nominal value.

To speculate in a species of securities liable to undergo such extreme and sudden changes irrespective of their intrinsic merits, must necessarily be a hazardous business to one not informed as to the manner in which these changes are brought about, nor likely to he advised as to the time of their occurrence. To most persone of small means dealings in these shares are therefore to he avoided. The rich and well-to-do, with their superior opportunities for obtaining correct information, both as regards the condition of the mines and these inside movements, and with their ability to better sustain losses, should they occur, can afford to take these chances; but not the poor man, who, if he desires to invest his money in this direction, should purchase shares in only productive, dividend-paying mines; or better, perhaps, if he does not care to go into the business himself, to become one of a small company to buy a cheap mine already opened, or to locate one, and having put it in shape, work it on joint account. The development of the Comstock lode is a heavy job, and should he left to the rich and experienced, who will he able to manage it without the assistance of those who are ignorant of the business, and have little to spare; and whose aid, while it can do little towards accomplishing the main object, may he the means of impoverishing the contributors in the end.

ARTESIAN WELLS.—One of the Pierce Well Excavators, which we recently illustrated in the MINING AND SCIENTIFIC PRESS, has been brought from the East hy the California Artesian Well and Mining Co., 202 Sansome street, and is now at work on a well at the Odd Fellows' cemetery. Only the earth auger is at present being worked, no rock having yet been met with. The whole apparatus, however, is ready for work to suit any kind of rock. It is all run by horse power.

THE Alaska Indians are rapidly preparing for war. The colonists are protected hy the vessels *Osprey* and *Oliver Wolcott*.

Arizona.—No. 1.

Capt. Wm. H. Seamans, who has recently returnsd from Arizona, hae kindly furnished ne many intercsting notes from different parts of Arizona visited hy him, which we ehall give briefly in this and future numbers of the Press.

In the Bradshaw Mountains.

The mountains known in Arizona hy thie gensral namo, comprise a group of ranges of different titles beetowed by the Spanish occupants of ths country, which may bo describsd as the coutinuation of the Sierra Madre of Mexicn, aud as terminating toward tho uorthwest at the great bend of the Colorado river near Callville, and to the south this particular range falle away into the great plain bordering upon the Salt and Gila rivers. They are in somc respects related to the Sierra Nevada, forming the western rim of the Colorado plateau; and containing granitic rocks with metalliferous lodes.

Theee mountains ars full of gold and silver-bearing vsins, with a etrong sprinkling of iron and copper. And, perhaps it ie hest to say, in ths heginning, that they have not yst heen efficiently developed throughout, to demonstrate which mines will hs finally worked to the greatest eatiefaction of the etockholder. The reader may form his own opinions of that eubject from the facts.

I have visited probably a hundred mines and mining claims in the Bradshaws in company with Prof. James Cherry, a fine geologiet and mining engineer, traveling with him nearly 200 miles and having tbe henefit of his knowledge and experience in mines and mining, which wae excesdingly intereeting and inetructivs to me. The Bradshaw region is divided into varioue mining districts—the Peck, Tiger, Lynx Creek, Turkey Creek, and Haeeayampa, besidee numerous othere.

The Tiger mine ie tbe representative mine in the Bradshawe, and it is attracting more attention, perhaps, at present, than any other mine in that region, having given its name to the district. It is 41 miles south of Preecott, and is reached by staging 31 miles, and tbe balance of the distance, 10 milee, by trail. The Tiger ie located in the heart of the Bradshaw range. It has a vein 75 feet wide between the walls, the ore body in the aggregate being about 12 feet thick. There are two main ore bodiee in two different seams, hesidee eeveral mineral-hearing etringere. The banging wall is of elate and the foot wall of granite.

The present working ehaft is down 200 feet. They have in the aggregate 2,000 feet of drifte and tunnels run, exposing a sulphuret ore rich in native eilver, of which the company claim to have over 300 tons on the dump expected to run $500 a ton. They have just completed new and powerful hoisting worke, and are sinking a new ehaft which it ie intended to carry down to a depth of 1,000 to 1,400 feet, in order tn etrike the ore body where the various seams and stringere are expected to come together. They have under contract and now on the way a ten-stamp mill, and a White's roaeter, which, it is expected, will be in opcration abeut the middle of May.

The euperintendent of the Tiger, Mr. Helm, saye he expecte to give back to the etockholdere iu about eix weeke after starting his mill, all the money they have invested, amounting to $200,000. I know of a mining engineer who offered to put up a $75,000 mill on their mine for them if they would givo him the first thirty days' run, and they declined the offer. There are now employed on the Tiger about fifty men, which in addition to those engaged in putting up the mill and placing the machinery, makes the Tiger one of the most lively mining camps in this part of the Territory. There are two boarding houeee, both full, and it is difficult to get accommodations of any sort on account of the number of people coming in.

It ie an exceedingly hard camp to reach, being enoompassed by bigh mountains, and is reached from the east by a difficult trail from the Peck mine, ten milee, or from the west hy tbe Walnut Grove road, which in placee ie almost perpendicular. The elevation of the Tiger ie about 6,500 feet.

At the time I was there it was closed to all outeidere. I got my facts mainly from the superintendent himself, but had them corroborated hy outside information, so that they may be depended upon as correct.

The other mines in the neighhorhood of the Tiger are the Hammond and Riggs, which is a prolongation of the Tiger ledge toward the northeast, and into which a tunnel has been run to a considerahle dietance, showing very favorable indications. There is also the Linn and the California, which claim to be upon the Tiger ledge. I think, however, that they are mietaken in that supposition. They also ehow favorable indications, and have been opened to a considerable extent.

We will furnish our readers with a hirdseye view of Arizona, in a seriee of articlee in the eneuing numbere of the Press,

---

There is now nearly $1,000,000 in eilver coine etored away in the vaults of the U. S. Mint in Careon City.

President Grevy has eigned a decreo pardoning 151 communiste,

Boiler Explosions.—No. 3.

[Written for the Press by H. W. Rice.]

Engineers who philosophize upon tho canses of boiler explosione, aro actuated by different motives. While one does so with the sole intentiou of ehowing how much he knows, another labors earneetly to elucidate or demonstrate eome favorite theory, which he claime to be tho only true cause of evsry explocion. Any uarrow-mindednees is fraught with great danger, as euch ideas coming before the minde of uuskilled pereone, carry weight which ie likely to prejudice eound judgmsnt. One engineer argues and maintaine that a boiler workiug under full preeeure, carrying its full amount of water, can have the water driven entirely away from tho eides of its furnace plates by heat from a coal or wood fire. In thie case, eteam is formed betwesn the hot plates and the water inside, and the water is not allowed to touch or coms in contact with the iron. Nn harm can come from believing thie theory, as it would cauee the boiler-maker to be careful and have large heating surface and dietribute the heat eqnally over it, and would caution ths engineer gainet overworking his hoiler. The theory that eome wonderfully explocive gas collects in boilers, ie a favorite one with those who are pleased to explain everything as very strange or myeterious. We know that water is composed of only two elements, alwaye found in exactly the eame proportions, and whether we call it "nrotoxide of hydrogen" or "aqua fluvialis," it does not changs the fact that it is water, and ie composed of oxygen and hydrogen only. It is true there is in rain-water the least preeence of nitric acid, in combination with ammonia, and water almost always contains a little organic matter; hut with all the reeearch that has been made, no demonstration of the existence of substaucee capable of producing explosive compounds has heen made.

I helieve that we are warranted in tbe conclusion that explocions are caueed either, first, by faulty construction; eecond, by careleesness or reckleeeneee in the management; tbird, by lack of knowledge and ekill. It would be a glorioue privilege if there wae a department in schoole where inetruction could be had, and where practice with working engines and hoilers could be obtained and their actual working eeeu and demonetrated. It would certainly be of more importance in eaving the lives of men than the practice of students in civil engineering, surveying and other hranchee of ecience wbere no lives are in danger from mistakes caueed by lack or want of skill in the art.

A eingular explosion of a threehing boiler—according to etatements obtained—occurred near Livermore, a few years ago, which killed the fireman, and made almost a worthlese wreck of the whole machinery. We eaw the wreck after it had been removed to our city, and the particulare of the affair were obtained from its owner, who was an eye-witnees of the explocion. As he claims to he a mecbanical engineer, practical in the uee of hoilers, and acted the part of an expert at the Coroner's inquest, we will give his own version, with his theoriee: The boiler wae furnished with a gauge or water glass on each end and two eets of gauge-cocks. It also had two eteam gauges, one on each end of the hoiler. Some time before the explosion it had been used with 150 pounds pressure for two days. At the time it exploded the gauges showed 79 pounds. This he saw himself not over one minute before the explosion took place. He is confident that the whole machine was raised to a hight of 100 feet in the air; at least it so appeared to him, and as it dropped on to ground lower than where it stood when it started, it was not in very good order for businees. We extract the following from the Livermore *Enterprise*, August 12th, 1876:

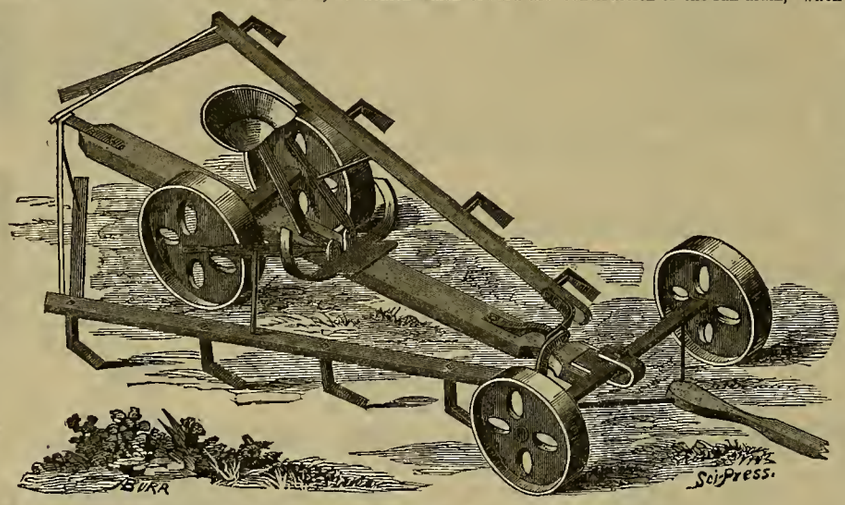
"The cause of the disaster, as stated by the engineer, appears to have been the unlevel situation of the engine. The ground where the engine stood, was sloping, and it was supposed that eufficient blocking-up on the lower end had not been done to correct the incline and level the engine. Some threshing had been done, possibly half an hour's work, when a stop was necessitated by the fall of the belt off the fly-wheel. Upon making tbe start after adjusting the belt, the blow-up occurred. The force of the burst was terrific. No time for thought or reflection, or presence of mind. A crack and a bang, and all was over. Three men were pitched off their feet and rolled down the hillside half stupefied; another was shot into the air and fell full 60 feet from the engine—this was the unfortunate fireman. The engine bounded nearly 50 paces, and fell, wheels uppermost. The concussion was so great that the men working on the derrick wagon and separater were struck down like so many tenpins. Large pieces of iron were projected with such force at the separator machine, as to break several parts of it. A piece of iron weighing quite 50 pounds, was discharged clear over the separator, and fell 193 feet beyond."

It would esem from theee recitale that this was ono of ths mysteries which could not be explained. If tbere are no mistakes, then it ie not safo to have steam boilers, and we ars liahle to wake up in eternity at any moment when we are paesing them, though they be carrying only a moderate pressure. It may uot be inappropriate to aseert that there is undouhtedly a true cause for every explosion. If the bearinge aud circumstances are carefully etudied the myetery would diseolve like dew in a eunny morning.

The Sutro Compromise.

A fiual agreement between Mr. Sutro and the Comstock mining companiss wae arrived at on Monday last, and will go into effect as soon ae the papere, which are now beiug drafted, can be signed, eealed and deliverod. The terme of the compromise are not to be made public till after the signing, but it ie generally understood that they are in eubstance the eame as the agreement drawn up and rejected some time ago. All the minee intereeted in the tunnel are included, and eome conceeeions have been made on both sides. Among the terme inserted is a clause to the effect that the companies ehall furnieh 1,000 men toward the conetruction of the suh-drain, for the completion of which 90 days' time ie given. There is no reason to believe that the execution of the contract will be deferred more than two or three daye, and immediately on its ratification the mine managers will take stepe towards utilizing the tuunel. At least 400 men will he sst to work on the euh-drain, and work on lateral shafts will also be commenced.

This will give employment to many minere now idle, and cause the newe of the compromise to be bailed with earnest eatisfaction by a large claes of people. It will probahly be a month or more, however, hefore the flooded minee can be drained, for at least that time is required for the completion of the suh-drain and the eetting up of the necessary machinery for pumping out the water.



P. S. RUSSELL'S IMPROVED CULTIVATOR.

Russell's Cultivator.

An engraving on this page ehowe an improved cultivator, recsntly patented through the Mining and Scientific Press Pateut Agency, by Prior S. Russell, of Rivereide, San Bernardino county. This is a wheel cultivator, and the frame carrying the teeth is arranged eo as to lift the teeth from the ground. The engraving ehowe ene sids raised aud the other down, so as to illustrate the two different poeitions.

The central beam is eupported on the axles and wheels, the rear axle heing mads short en that the wheels may be inside the timhers or winge which carry the teeth.

A tongue is attached to the front axles, to which the horsee are harneessd, eo that the driver on his seat has complete control over the cultivator, the front axle being swiveled to the beam, and the cultivator can bs guided with great ease.

The cultivator proper, formed of the two beams or wings, ie A-shaped. The front ends havs curved hars attached to them, which hare aro pivoted on the bolt on the heam, as ehown, so that the wiugs may he raised and lowered at will. At the rear ends of the winge are the brace-bare, pivoted to the rear end of the beam. In the center of each wing is an upright rod, faetened to the hand-levers, which levere are pivoted to the central heam, as shown, and ratchet-bare on the central beam lock the levere in any desired position, so that the eide winge may be kept down or up, as desired. Thie raieiug aud lowcring of the eide wings ie poeeible for the reason that they are pivoted or hinged to the center beam at both ende. As these wings can be raised entirely clear of the ground, the cultivator can travel to and from the field with great facility.

Either wing may be moved independently when at work, to clear it of weede or raise it over rocks or other obetructions. At the rear end of the brace-bare on each eide extende downward a rod, at the lower end of which is secured a knife or blade, the other end of which is fastened to the rear tooth of the wing. These hlades or knives are secured in euch a manner, that, when the eide winge are down and at work, the knivee move horizontally through the earth and cut off any weeds which may bave escaped the teeth, leaving the ground perfectly clean.

The wheele are made broad on the face, so as not to eink into the ground or allow the cultivator teeth to go too deep. The teeth are made with their points inclined, eo as to turn or break the eoil up as they are dragged through it; but the wheels prevent their digging eo deep ae to make a heavy draft for the team.

The arrangement of the wings with teeth aud cuttere, eo as to be raised clear of the ground, enables the operator to travel to and from the field with facility, and either wing can he raieed while at work and cleared of weede or rubbish. Any weeds which escape the teeth are cut by the cuttere, eo that the field ie thoroughly cultivated.

This cultivator is intended principally for orchards and vineyard work. It pulverizee the ground to the depth of four or five inches, at the will of the operator; and hy means of the tongue and seat the driver has complete control over hie team and machine, thereby heing able to work close to the rowe of trees or vinee without injuring them. For further information, the inventor may be addreseed as above.

The Quicksilver Mines of Old Spain.—We have received a pamphlet of eome 50 pages, heing a memoir prepared by M. H. Kuss on the "Quicksilver Mines and Worke of Almaden." The contents of this pamphlet, translated from the French hy S. B. Chriety, appeared originally in a series of articles published in the Mining and Scientific Press, where they awakened so much interest ae to justify their collection and reissue in the above form. This little work givee a full, intelligent and reliable account of the geological depoeite at Almaden, as well also as a complete description of the exploitation of theee celebrated mines, their administration and history, and the metallurgy of mercury as practiced there. The book can be obtained from the publishers, Dewey & Co., No. 202 Sansome etreet, S. F., who forward it for 50 cents per copy, post-paid.

Hercules Powder.—We call the attention of our mining readers accustomed to use high explosivee to the card of the Hercules Powder Company, which appears in auother column. We have received this week a pamphlet which appears to contain a great deal of information concerning Hercules powder and other high explosives, and to which we ehall refer after having an opportuuity for a more careful examination.

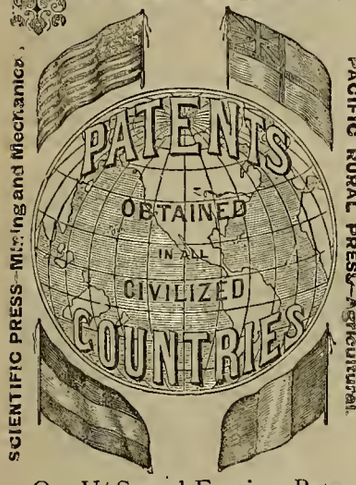
Six murderers were hanged on the 14th, two in Oregon, one in this State and three in New England. Capital punishment appeare to he gaining favor.

About 6,000 people were drowned by the Szegedin flood.

A Bruckner Pulverizing Barrel, for cruehing oree, bas been set up at the Central mills, on Berry etreet, between Fourth and Fifth, and is now at work. Mining men will do well to examine this barrel, which has been very succeeeful wherever tried.

The Tulare valley farmers are arming and organizing military companies under the State provisione, to resist the occupation of their lands by corporatione.

DEWEY & CO'S
SCIENTIFIC PRESS
Patent Agency.



Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system and intimate acquaintance with the subjects of inventions in our new community. All worthy inventions patented through our Agency will have the benefit of a description or an illustration and explanation in the MINING AND SCIENTIFIC PRESS or the PACIFIC RURAL PRESS. We transact every branch of Patent business, and obtain Patents in all civilized countries. The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obtained through our Agency. The files of cases and official records in our office, our patent law and scientific library (already the lar gest west of the Mississippi), are constantly increasing. These facilities, with the accumulation of information of special importance to our home inventors, by the experience of its proprietors in an extensive and long continued personal practice, gives them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

DEWEY & CO.,
Patent Solicitors
No. 202 Sansome St.. S. F.

A Library for Inventors.

We have at our patent offices, No. 202 Sansome street, corner Pine, a complete set of Patent Office reports, containing engravings and claims of EVERY PATENT ever issued in the United States.

We have also a complete set of the MONTHLY VOLUMES issued by the Department, with full detailed description and large drawings of all the patents issued since the time when these volumes were first published.

A set of all the LAW BOOKS ON PATENTS is also on our shelves ready for reference. We have also the British Commissioners reports, Canadian Patent Office reports for all British North America, full files of MINING AND SCIENTIFIC PRESS, PACIFIC RURAL PRESS, *Scientific American*, *Scientific American* supplement, *American Artisan* and other American and foreign scientific and mechanical journals, as well as mechanical dictionaries chemistries, encyclopedias, and other works of reference.

Inventors and patentees are WELCOME TO EXAMINE at their leisure any of the books in the above sets, and we shall be glad to give them any assistance in hunting up what they want.

Our library is the most complete of its kind on the Pacific Coast in every respect, and we are continually adding to it as occasion demands. DEWEY & CO.,
Patent Agents and Publishers,
No. 202 Sansome street, corner Pine, San Francisco

Ingersoll Rock Drills.

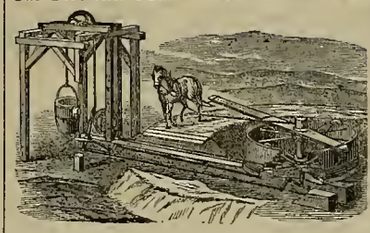
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse ca easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS, RIX & CO., 18 & 20 Fremont St., San Francisco.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and placer mining in various parts of the Pacific Coast. Over five hundred orders have been filled, and the demand is constantly increasing. A large number of these Plates were sent to Snake River mines, Idaho, last year, and a great many orders are being filled for them this season. Circulars containing full instructions for working these Plates sent with each order. Old Mining Plates bought or taken in exchange for new Silver Plated Plates, and full value allowed. Gold extracted from old Plates at a moderate cost by a new and economical process. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed.

Mining Men and the public generally are cautioned against unprincipled and irresponsible parties traveling through the country, endeavoring to secure orders for very inferior qualities of Silver Plated Mining Platee.

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,

North Bloomfield, Nevada Co., Cal., October 1st, 1878.

[Continued from page 181.]

REESE RIVER DISTRICT.

MANHATTAN.—*Reveille*, Mar. 15: The ore body being developed in the 517 drift of the Curtis shaft improves daily as the drift is extended. It has now been advanced in the ore some 30 ft aud a stope is being opened up. The 560 stope is now only being worked on the bottom ledge and contains some very rich ore. The stope in the 825 level carries a large ledge of high-grade ore. Sinking the winze in the 600 west drift of the North Star shaft continues with good progress. A drift has been started on the ledge found in the footwall of the 600 east drift which carries very good ore. This body of ore is directly under that now being worked on the 560 level of the Curtis shaft and undoubtedly continues up to tbis level which is about 130 ft on the ledge.

SILVER STATE DISTRICT.

THE BLUE BELL MINE.—*Silver State*, Mar. 17: Col. Buel has attained a depth of 23 ft on the Blue Bell mine. The ledge looks well in the bottom of the shaft. The lead is four ft and one inch wide, by actual measurement, at the bottom of the shaft. The country rock is much softer than it was near the surface, and tbe ledge dips at an angle of about 50°, west.

COLORADO.

HARRINGTON & SPRINGFIELD.—*Courier*, Mar. 13: Tbe property is opened by an adit 230 ft long, that has been run on the Harrington lode, and at a point 156 ft from the adit's mouth a crosscut has been driven south 65 ft to the Springfield, which has a sharp dip towards the former, and probably joins it at no great depth. This crosscut shows the Harrington lode to be eight ft wide, then comes a body of country rock nine ft tbick, then crevice rock for 24 ft, which is probably the main lode, aud then country again for 22 ft, when the Springfield lode is reached. At the discovery of the Springfield there is a fine looking streak of galena ore, but where the crosscut intersects it but little ore is in sight and that badly scattered through the quartz. A short distance beyond the crosscut, the main adit runs into the large lode and follows a vein of gouge and decomposed ore near the north wall for a distance of 60 ft. The lode is large and soft, so that at tbis depth, about 150 ft perpendicular, it is subject to the action of water, which has decomposed the ore and nearly the whole mass is more or less stained from the effects of it. For the last 60 ft the adit bas followed a slip in the crevice, upon which was a vein of gouge and ore that has increased in size as the drift has been driven, until now in the breast it is about one ft wide at the top and two at the bottom, and also carries considerable solid as well as decomposed galena; solid chunks as large as a hen's egg now being found in the vein. At this point work is now going forward, it being the desire of Mr. Harrington to reach solid ore as soon as possible.

THE EQUATOR.—This company has started a crosscut tunnel at the foot of the mountain in lower Silver Dale, that will cut their lode at a depth of between 500 or 600 ft; or in the neighborhood of 200 ft deeper than the Marshall tunnel cut it. The tunnel will be nearly 1,000 ft long, and 7x8 ft in size, large enough for a double track. It is being run by contract, by Richard Nankwell and James Coran, who have completed 50 ft and started on their second 50-ft contract.

IDAHO.

SNAKE RIVER PLACERS.—Cor. *Statesman*, Mar. 11: Mr. Corker and Mr. Corbell came down from Salmon Falls and began work, taking out a ditch from Suake river to work tbeir claims. They have ordered plating from San Francisco and will open up soon. Messrs. P. H. Clark and William McGinuess are busy at work taking out a ditch for their ground at the mouth of Cold Spring creek. They have sent for plating and will be running in about two weeks. The miners are rushing iuto the Cold Spring district, locating ground very fast. Mr. Black, of Black's station, is in this district and has located 160 acres for a company of Boise men. Mr. W. L. Thurman has a man out prospecting for him and three others, and has located one half a mile below the mouth of Cold Spring creek. Mr. A. L. Richardson, on his way through to Salt Lake, located alongside of Thurman's claim. There are a lot of men just arrived here to-day from Nevada.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

JOHN G. M. Co.—Capital, $10,000,000. Directors—Wm. Kobl, C. T. Bridge, W. E. Sill, W. T. Jones and D. T. Davies.

OLETA G. & S. M. Co.—Capital, $10,000,000. Directors—Albert Jenks, J. J. Scoyille, W. T. Henson, Henry Oerdes, C. Gierrez, Percy Freligrath and F. E. Birge.

NORTH MEXICAN S. M. Co.—Object: To operate in Virgiuia district, Story county, Nevada. Capital, $10,000,000. Directors—B. W. Mudge, F. P. Howard, W. H. Weidman, C. C. Fisher and T. A. Mudge.

McKINLEY CON. G. M. Co.—Object: To operate in Bodie district. Capital, $10.000,000. Directors—I. W. Gashwiler, T. H. Lawler, William H. Sharp, E. B. Clement and W. H. V. Cronise.

MONITOR M. Co.—Capital, $10,000,000. Directors—Thomas Price, J. P. Allen, H. Mayers, George W. Smiley and J. S. Allen.

MAMMOTH M. Co.—Object: To operate in Humboldt county, Nevada. Capital, $10,000,000. Directors—J. H. Crossman, G. B. Briter, Edward Hall, B. W. Mudge and W. T. Robinson.

SAN GERONIMO G. & S. M. Co.—Object: To operate in California. Capital, $10,000,000. Directors—A. S. Higgins, C. B. Higgius, A. Peck, George Stone and E. A. Peck.

IVANHOE M. Co.—Capital, $10,000,000. Directors—R. C. Hooker, George B. Root, W. W. Foote, Frank Vernon aud J. F. Cowdery.

AMADOR TUNNEL, MILL AND M. Co.—Capital, $2,500,000. Directors—Charles J. Pilsbury, Arthur B. Cruickshank, Edward C. Mactarlain, J. H. H. Williams and W. L. Locke.

McKINLEY CON. G. M. Co.—Object: To operate in Bodie district. Capital, $10,000,000. Directors—f. W. Gasbwiler, Thomas H. Lawlor, William H. Sharp, F. B. Clement and W. H. V. Cronise.

AMAGOR TUNNEL, MILL AND M. Co.—Object: To mine in California. Capital, $2,500,000. Dircetors—Charles J. Pilsbury, A. B. Cruikshauk, E. C. Macfarlan, J. H. H. Williams and W. L. Locke.

ÆTNA M. Co.—Object: To mine in Nevada. Capital, $10,000,000. Directors—Thomas H. Lawlor, J. S. Benear, A. F. McGrew, C. C. Conger and C. M. Arnold.

BLUE BELL M. Co.—Object: To operate in Humboldt county, Nevada. Capital, $10,000,000. Directors—L. S. Robinson, J. W. Gashwiler, M. L. McDonald, J. M. Getchell and W. H. Sharp.

GORGON CREEK M. Co.—Capital, $100,000. Directors—J. D. Oray, J. W. Musser, W. C. Chapin, F. D. Brandon and B. C. Jackson.

GOLG BANK GRAVEL M. Co.—Capital, $100,000. Trustees—J. F. Miller, J. Arthur Fairweather, E. L. Willard, G. A. Treadwell and O. D. Squire.

IT is reported that the country is flooded in Big Valley, Modoc county, so that the mail is carried in boats over the road for a long distance.

IT is announced that on April 1st there will be a general reduction in the freight charges of the Virginia and Truckee road.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. ANG FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington. D. C.

FOR THE WEEK ENDINO MARCH 11TH, 1879.

213,154.—IMPROVEMENT IN CONSTRUCTION OF BRIDGES—E. Williams, S. F.
213,153.—CAR BRAKES—A. Weymouth, Livermore, Cal.
213,117.—AXLE FOR VEHICLES—E. E. Lincoln, San Jose.
213,052.—IMPROVEMENT IN LAMPS—D. Lubin, Sacramento, Cal.
213,134.—IMPROVEMENT IN DENTAL PLUGGERS—H. Richmann, S. F.
7,106.—LUBRICATING COMPOUND—Trademark—Bean, Bracey & Co., Virginia City, Nevada.

FOR THE WEEK ENGING MARCH 18TH, 1879.

213,399.—BIT STOCK—L. C. Di Bert, S. F.
213,386.—VEHICLE SPRING—O. S. Carville, S. F.
213,382.—APPARATUS FOR OBTAINING METALLIC COPPER FROM ITS SOLUTIONS—C. C. Bitner, Spenceville, Cal.
213,400.—WAGON BRAKE—J. F. Ditsworth, Austin, Nev.
7,120 to 7,124 inclusive.—CANDLES—Trademark—W. T. Coleman, S. F.
7,125.—CLOTHING—Trademark—Heynemann & Co., S. F.
7,112.—CANDLES—Trademark—Castle Bros., S. F.
7,114.—CATHARTIC MEDICINE—Trademark—E. DePrati, San Francisco.

The names of the following persons and the patents granted them have through some irregularity been inadvertently omitted from the lists which we print each week:

FOR THE WEEK ENDING JANUARY 7TH, 1879.

211,125.—HYGRAULIC PUMPING SYSTEM—W. P. Barclay, Virginia City, Nevada.
211,235.—DEVICE FOR OBTAINING MITER BEVELS—W. Harbaugh, Alameda, Cal.
211,155—DEVICE FOR PREVENTINO OVER-WINDING—H. C. Harrison, Eureka, Nev.
211,248.—AMALGAMATOR—J. Michel, Nevada City, Cal.
211,269.—HAY RAKE—F. Shedd, Shedd Station, Ogn.

FOR THE WEEK ENDING JANUARY 14TH, 1879.

211,425—SULKY PLOW—J. Price, San Leandro, Cal.

FOR THE WEEK ENGINO JANUARY 28TH, 1879.

211,714.—WINGMILL—J. R. Dixon, Fresno, Cal.
211,763.—SIGHT FOR FIRE-ARMS—W. Matthews, Camp Bidwell, Cal.
211,756.—MINING CAR TRUCR—W. McCaskell and A. J. Munchard, Virginia, Nev.
211,794—SHOE FASTENER—I. J. Saunders, Davisville, Cal.

FOR THE WEEK ENDINO FEBRUARY 4TH, 1879.

212,066.—RATCHET DRILL—J. C. Steber, S. F.
211,939.—AMALGAMATOR—W. S. Shotwell, S. F.
211,833.—ELECTRIC SIGNAL FIRE HOSE—J. Bucbtel, Portland, Ogn.
211,999.—SUSPENGERS—H. M. Heinemann, S. F.
212,037.—MOTOR ENGINE—E. J. Molera and J. C. Cebrian, S. F.
212,038.—MOTOR—E. J. Molera and J. C. Cebrian, S. F.
212,039.—FLUIG MOTOR—E. J. Molera and J. C. Cebrian, S. F.
212,040.—REGULATOR FOR ELECTRIC LIGHTS—E. J. Molera and J. C. Cebrian, S. F.
211,936.—WINDING ATTACHMENTS FOR CLOCKS—S. Serighelli, S. F.
211,937.—EXPANSION PULLEY—S. Serigbelli, S. F.

FOR THE WEEK ENDING FEBRUARY 18TH, 1879.

212,347.—TOBACCO CUTTING MACHINE—L. Bauer and J. Seitz, S. F.
212,432.—RAILWAY CROSSING—W. B. Bernard, Sacramento, Cal., and J. D. Perkins, Elyria, Ohio.
212,493.—BILL FILE—E. H. Owen, Los Angeles, Cal.
212,331.—FLAVORING COMPOUND FOR TOBACCO—D. Sternberg, S. F.

FOR THE WEEK ENDING FEBRUARY 25TH, 1879.

212,591.—ENGINE—R. J. Cartmel, Santa Rosa, Cal.
212,664.—PULVERIZING MILL—J. T. Davis, S. F.
8,601.—FIRE-ARM—Re-issue—W. R. Finch, Eureka, Cal.
212,698.—STOVE—H. L. Howse, S. F.
212,739.—PACKING FOR STUFFING BOXES—G. C. Phillips, Silver City, Nev.
212,770 and 212,771.—CAR TRUCKS—George Vincent, Stockton, Cal.
212,775.—DERRICK-STAKE—R. P. Williams, Alameda, Cal.
212,780.—PADLOCK—N. A. Young, Healdsburg, Cal.

Notices of Recent Patents.

Among the patente recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

WAOON BRAKE.—J. F. Ditsworth, Austin, Lander Co., Nev. Dated, March 18th. This improved wagon brake consists in attaching to the rod connecting the brake bar with the roller, a case containing a spiral spring, through which the connecting rod passes. A nut on the rod under the case bears against the spring, when the brake is thrown on, so that in case a wheel is not perfectly round and the high place on the wheel etrikes the brake shoe when the brake is on tight, there is no danger of breaking the rods or of locking the wheel in one place so as to wear out the tire at one point. Suitable nute are placed in the connecting rod for regulating the tension of the spring, and also for preventing the rod coming too far back in case the spring ie hroken or hecomes too loose. With an ordinary hrake, the bar is connected to the roller by a solid connecting rod running to the short arm iu tbe roller. In case the wheels are not perfectly round when the brake is on tight and the high place in the wheel etrikee the block, the wheel will etop rotating and the part of the tire on the ground will be subjected to unnecessary wear. The tire will, therefore, soon become worn through at that point. Again when the wheel strikes the brake in the high place, it causes a jar on the brake frequently causing the hrake to give way. Very many of the accidents from brakes giving way have been occasioned by this defect. With this improved brake, when the high place in the wheel strikes the brake blocks, the spring in the case attached to the brake bar will give enough to allow the high place to pase the blocks without causing the wheel to drag, saving the tires from wear and causing no jar to the brake rods. When the brake is suddenly thrown on, and while its action is just as effective, it comes up with an easy motion and no jar. This method of connecting the brake bar with the levers tends also to keep the wheele round, as wherever there is a tendency to hulge, there a greater pressure is exerted. The spring being enclosed in a ehell is out of the way of the duet and dirt, but is easily accessible for repair or replacement, by separating the two sides of the ehell.

CARRIAOE SPRING.—Orrin S. Carvill. Dated March 18th. This invention relates to a novel improvement in the construction of springs and gear for carriagee and other vehiclee, and it consists mainly in the combination with the wooden side bars of a huggy of a central longitudinal eupplemental steel spring, so arranged and connectcd with the side bars that it will take a considerable portion of the strain when a heavy load is brought upon it, and by its assistauce to the wooden side bare greatly adds to the elasticity of the buggy. It further consists in the employment of a peculiar clip by which the side bars are attached to the holster and the rear axle bed, and by which they have a free and independent motion upon their points of attachment, and the axle bed or bolster will not be rocked back and forward by the vertical movements of the side hars and epring.

News in Brief.

HOSTILITIES are pending between Chile and Peru.

EBERHARD FABER, the great lead-pencil man, is dead.

ALSACE and Lorraine are to have a special cabinet.

THE work of rebuilding Reno is progressing rapidly.

TWENTY THOUSAND Russiane are moving into Turkistan.

IRON is to be supplanted by steel in the building of ships.

MERCED COUNTY is alive with vigorous young echool marms.

RAILROAD communication has been reopened above Maryeville.

SPANISH public opinion is unfavorable to the new Ministry.

LOUISVILLE is among the cities that are financially swamped.

THERE is a widely-spreading republican element in Brazil.

THE Russian police continue to make arreets for secret printing.

A PRAIRIE fire near Abilene, Kansas, nearly destroyed tbat town.

A HEBREW western colonization scheme is active in New York.

TELEPHONES are heing introduced into almost every town in Oregon.

FIVE Chinamen have been killed by Sheephead Indians iu Utah.

A DOZEN vessels will go north thie epring in the codfishing business.

THE reduction of the wages of laborers in England is very general.

THE new Constitution will technically relieve Chinamen from poll-tax.

SUTRO has at last effected a compromise with the Comstock companies.

BULLION continues to flow into Carson, Nev., from the eouthern country.

THE Western Electric Light Co. are running their elevators by electricity.

TWENTY-FIVE families of Mennonitee in Manitoba cultivate 10,400 acres.

A LOT of catfish have been put in Napa river some distance above tide water.

IT is estimated that there are at least 800 Chinese in and around Red Bluff.

THE Government is about to issue ten-dollar four per cent. treasury certificates.

THE growing crops in Washington Territory look finely, with no chance of failure.

AN excursion from the East to meet Gen. Grant on his arrival here ie talked of.

Two men were killed in a Pennsylvania coal mine, recently, by the fall of roof rock.

THE Southern Pacific railroad ie boring artesian wells in the California desert.

THE tramp who outraged Mrs. Truesdel at Newport, Ky., was lynched by a mob..

THE ground was found to be frozen to the depth of three and a half feet in a New Haven street last week.

The "Little Wonder" Self-Calculating Sample and Button Weigher.

EDITORS PRESS:—Please allow me epace for answering numerous inquiries from your readers as to the general advantages and appliances of the above, recently patented apparatus.

1. It is more especially intended for those who can aesay by the blow-pipe, being surpassingly delicate in action and very portable, as well as self-calculating for dollars per ton on gold and silver, and percentage of lead, or other base metals.

2. It may be used for buttons from "furnace aesays," either by its self-calculation, or by ordinary eystems of weights.

3. It must supersede all other weighers for explorers and hlow-pipists, as it is not only cheaper but much more eusceptible, readily used, and portable.

4. It is explained on its face, and those who cannot even read figures may value with it.

5. To my past pupils I may eay, that they and all other blow-pipists are laboring under difficulties in weighing which this will lessen, to an almost incredible degree.

6. Its cost is only $25, including two weighere with weighte, and all other necessary tools.

J. S. PHILLIPS.

SPAIN boasts of 92 Dukee, 866 Marquises, 632 Counts, 92 Viscounts, and 98 Barons, besides 44 ennohled foreigners.

THE German Tariff Commiseion hae determined to shut out of the Empire American cattle and British coal.

FRESH attractions are constantly added to **Woodward's Gardens**, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and tbe Pavlliou performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

And in accordance with law, and an order of the Board of Directors, made on the 21st day of January, 1879, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the Company, No. 330 Pine street, Room 4S, San Francisco, California, on the 26th day of March, 1879, at the hour of one o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

G. M. CONDEE, Secretary.

Office, Room 4S, No. 330 Pine St., San Francisco, Cal.

Office Wide Awake Prospecting and Mining

Company.—No. 232 Sutter Street, San Francisco, Cal., February 1st, 1879. Location of works, Picket-Post, Pinal County, Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the first day of February, 1879, an assessment (No. 8) of four cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 2, No. 232 Sutter Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fifth day of April, 1879, to pay the delinquent assessment, together with the cost of advertising and the expenses of sale. By order of the Board of Directors. C. HILDEBRANDT, Secretary.

POSTPONEMENT.—The delinquent day of the above named assessment has been postponed until Tuesday, the First day of April, 1879, and the day of sale until Thursday, the First day of May, 1879, at the same hour and place. By order of the Board of Directors.

C. HILDEBRANDT, Secretary.

San Francisco, March 1st, 1879.

Summit Mining Company.—Location of

Principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 7,) levied on the 4th day of February, A. D., 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Byers, W T	33	700	35 00
Edwards, J E	39	700	35 00

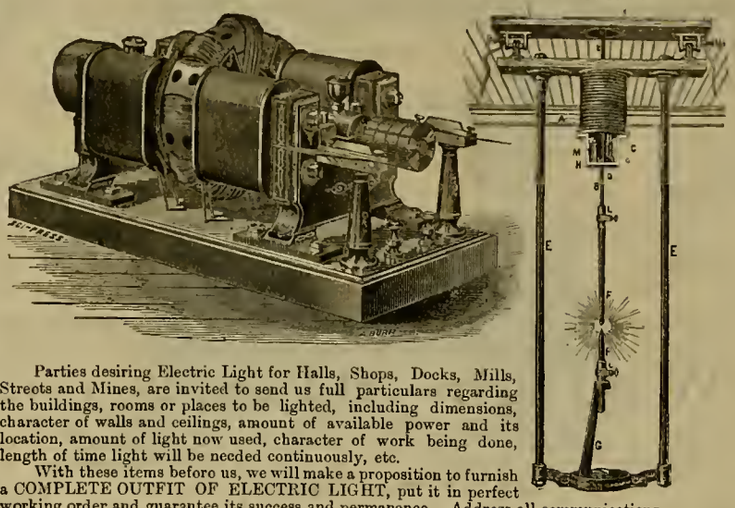
ELECTRIC LIGHT.

BRUSH PATENT.

The Best, Cheapest, Cleanest, and Most Powerful Light in the World.

In daily use at the Palace Hotel and the Union Iron Works, S. F.



Parties desiring Electric Light for Halls, Shops, Docks, Mills, Streets and Mines, are invited to send us full particulars regarding the buildings, rooms or places to be lighted, including dimensions, character of walls and ceilings, amount of available power and its location, amount of light now used, character of work being done, length of time light will be needed continuously, etc.

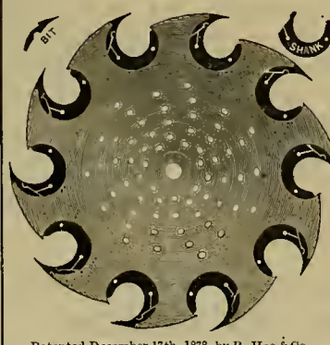
With these items before us, we will make a proposition to furnish a COMPLETE OUTFIT OF ELECTRIC LIGHT, put it in perfect working order and guarantee its success and permanence. Address all communications,

S. F. TELEGRAPH SUPPLY CO.,

WM. KERR, President,

San Francisco, Cal.

THE VENTILATED (PERFORATED) SAW.



Patented December 17th, 1878, by R. Hoe & Co.

The diameter of the body of the plate in this cut is contracted, in order to show the teeth more plainly.

Our Chisel-tooth Saw has already taken the lead, and is rapidly superseding all others, and now we have the pleasure of calling your attention to still another IMPROVEMENT which we are placing on them without additional charge.

The ventilators (holes) cause the plate to shrink equally in the process of hardening, thereby avoiding the injury resulting from warping and subsequent trueing with the hammer, to which solid plates are subjected. They also take the chip out of the cut, and the circulating of the air through them keeps the saw cool.

Office of Hanson, Ackerson & Co.,
Manufacturers and Dealers in Lumber, Etc.,
Tacoma, Wash. Ter., Feb. 14, 1873.

Messrs. Tatum & Bowen, 3 Fremont St., San Francisco.

GENTLEMEN:—The 60-inch Perforated Chisel-Tooth Saw purchased from you in December last has been in constant use since received, doing its work faithfully, and we consider it the best saw in our mill. SLOWER TO HEAT than solid saws, standing up to its work in all kinds of timber, and good for NINETY THOUSAND FEET A DAY. We take great pleasure in recommending your Perforated Saws for mills engaged in cutting large timber.

Yours Respectfully, HANSON, ACK. IKSON & Co.

Sharp, round and ready to run the moment received.

Can be kept so without expenditure of skill or time.

When dull, a boy in five minutes can insert a set of sharp teeth in largest saw, without removing from mandrel.

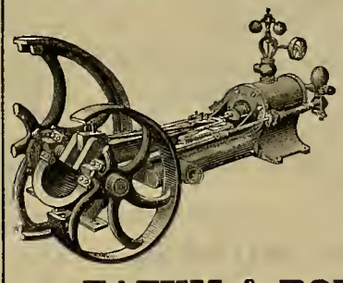
The teeth, being firmly held, without rivets, screws, or keys, will stand the heaviest feed, and cut the least kerf.

Teeth only 3½ CENTS each.

Address TATUM & BOWEN, Sole Agents,

SEND FOR CATALOGUE. No. 3 Fremont Street, San Francisco.

THE BALL PATENT VALVE ENGINE.



The valve is in two parts and connected by circular sleeves which allow each part to be adjusted by steam pressure to its own face and to follow the wear.

The sleeves have rings which prevent the steam from escaping between them. The pistou has two full sets of Steam Packing Rings, each set being composed of six pieces. They take care of themselves and need no looking after.

The rim of the balance wheel is in three pieces, the object being to have a light or heavy wheel, a very desirable feature in boring oil or artesian wells. Can be attached to boiler or bed.

It is cheaper, and warranted to run longer without attention or repair than any engine in use.

Price, cylinder 9x12, with Heater, Governor, Pump, Bolts and everything complete, $500. Weight, 3,000 pounds. Duplicates of all parts kept on hand. Engines No. 952 and No. 962 on hand in San Francisco.

Reversible engines of same style—same price.

300 Revolutions, 40 horse-power, price, $500.

High Speed System, dispensing with large Pulleys and Heavy Gearing.

TATUM & BOWEN, Sole Agents,

THE SAFETY POWDER COMPANY,

San Francisco, Cal.

CARTRIDGE.

GEN. W. S. ROSECRANS, President.

Fuse Lighter and Fuse.

COL. SAM'L O. GREGORY, Secretary.

Safety Cap and Fuse.

Electric Cap.

Safety Powder, Caps, Electric Caps, and Fuse Lighters.

Under a series of U. S. Patents, after long and carefully conducted experiments and thousands of tests, this Company is prepared to manufacture and supply, for Mining and Engineering Works, the above named articles at prices and on terms as favorable as articles of similar grades are now supplied in this market. Our Powders contain no Nitro-glycerine, no Nitroline, no Gun Cotton, no Fulminates, and are free from the unavoidable dangers in manufacturing transporting, handling and using of all high grade explosives which contain those elements.

Cold does not affect them. They cause no headaches or other inconveniences in handling, and the smoke from their explosion contains no poisoning or sickening vapors.

Their blasting force, with slight tamping, at least equals that of any Powders now used, but they admit and require strong tamping to bring out their immense and peculiar lifting power which follows their detonating work. They should be fired, therefore, by our

Safety Cap,

Which allows tamping without danger. They can be fired by any caps now employed in blasting, but the use of these is always dangerous with any Powder, and the loss of the throwing power resulting from lack of tamping renders it with our Powders doubly objectionable.

Our SAFETY CAPS have twice or thrice the force of triple Giant Caps. When set on fire they do not explode, but merely burn off, and are perfectly safe in transporting and in tamping.

In round tin boxes, 50 cents.

The Safety Fuse Lighter,

Cheap, handy and sure to light the Fuse upon the end of which it is fastened, only needs a trial to be appreciated by every miner who is up to "snuffs." 25 Cents per box; sent by mail.

Safety Fuse,

Equal to the best in the market, will be supplied at the lowest market prices.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature, thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

Market, head of Front St., San Francieco

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia, and to other parts of North and South America. Estahlished in 1860, it has long been the leading Mining Journal of the continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

Paul's Dry Amalgamating BARREL PROCESS.

This is the most perfect of all systeme for amalgamating the precious metals—more especially gold, for which it is absolutely perfect, the per cent. of metal obtainable being only governed hy the fineness of reduction of ore. It will gather the flour gold with the same readiness as the coarse. The machinery and operation is simple and practical—not requiring skilled labor. Its efficiency is verified hy mills in practical operation. I will contract for mills of 10, 20, or 50-ton capacity per 24 hours. Pamphlets, explaining the process more fully, forwarded on receipt of address. For further particulars apply to

ALMARIN B. PAUL,
Room 20, Safe Deposit Building, San Francisco.

SAN FRANCISCO, SATURDAY, MARCH 29, 1879.

VOLUME XXXVIII Number 13.

Michel's Improved Amalgamator.

We illustrate herewith an improved amalgamating pan, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Justin Michel, of Nevada city, Cal. The invention consists in a pan provided with a bottom gradually descending from the center to the circumference, and provided with a flaring rim, which merges into an outwardly curved projection or rim, whereby a more rapid feed and circulation are kept up, the form of the bottom always starting the current at once outwardly, and aiding the centrifugal action.

A represents the amalgamating pan with enclosed sides, *X*, mounted on the usual standards, and having the pulley, *B*, shaft, *C*, gear, *D*, and pinion, *E*, as shown, for directing the power to the operating parts.

In the center of the pan is a hollow standard, *E*, which projects upwardly above the top of the pan and inside of which plays the vertical shaft, *F*, having the pinion, *E*, at its lower end engaging with the gear, *D*. A collar, *G*, is formed on this vertical shaft, which revolves on top of the hollow standard, thus forming a bearing for said shaft. A hollow cylinder or sleeve, *H*, slips down over the shaft, *F*, and standard, *E*. This sleeve has an extension, *I*, made somewhat smaller than the sleeve, and inside of which the upper end of the shaft projects, the sleeve itself enclosing the standard, *E*.

At the point where the sleeve and extension join, an offset is formed as shown, the sleeve being larger in diameter than the extension, and at the same time thicker. Feed holes, *J*, are bored or formed vertically down through the sleeve, *H*, commnnicating with the center of the pan, as shown. Several of these feed holes are formed in the sleeve, and the pulp is fed to the pan through them.

An upwardly extending rim or flange, *K*, is formed on or attached to the upper end of the sleeve, *H*, and answers as a sort of a hopper above the feed holes. The ore fed into this ring or hopper, passes down through the feed tubes to the center of the pan, so that a sort of funnel is formed for the continuous introduction of ore and water. To the lower part of the sleeve, *H*, are attached the muller rings or frames, *L*, to which are secured the shoes, *M*, by dovetail mortise and tenon.

The dies, *Q*, are so placed in the bottom of the pan as to leave a groove, *N*, around the center of the pan, into which quicksilver is placed. The lower part of the sleeve is cut away above this groove, *N*, as shown at *O*, so that amalgamation may be accomplished by centripetal injection, the centripetal force being induced by means of the curved rim, *P*, as hereinafter described.

The dies, *Q*, are so formed as to leave a groove, *R*, around the pan, into which quicksilver is introduced for amalgamation by centrifugal injection, the centrifugal force being induced hy the rotation of the arms and shoes attached to the sleeve.

On the upper sides of the arms or frames, *L*, are placed adjustable agitators, *T*, which, hy their peculiar shape, regulate the centrifugal motion of the water. These agitators have a set screw or common screw, *S*, hy which they are attached to the arms or frame, and which will hold them in any desired angle or position.

The pan has an inwardly-projectiug curved rim, *P*, which tends to direct the heavier particles of ore to the center. The lighter particles flow over the edge of this rim, and fall into the channeled plate or conveyor, *T'*, passing from this through the spout, *U*, to the settlers, or wherever it is desired to lead them.

A feather, *V*, is formed in the upper end of the vertical shaft, *F*, which engages with a longitudinal groove formed in the extension, *I*, of the sleeve, *H*, so that when the shaft, *F*, is set in motion, this motion is imparted to the sleeve carrying the arms and shoes.

In order to be able to regulate the hight of the shoes and dies, a set screw, *V*, passes down through the upper end of the extension, *I*, and its lower end rests on the top of the shaft, *F*, a suitable hearing being formed at that point. As this set screw is screwed through this extension, hy turning it the extension may be raised or lowered, thus raising or lowering the sleeve carrying the arms or shoes. A discharge pipe, *W*, on the lower side of the pan, is used for drawing off the contents when it is desired to clean up the pan.

It will be seen from the foregoing description that contiuuous feed and discharge may be maintained in this improved pan. The pulp may be lead by appropriate means into the ring or receiver, *K*, and is directed by the holes in the shell down to the bottom of the pan, where it falls into the quicksilver in the central groove, *N*. The natural centrifugal motion imparted to the mass of pulp by the motion of the shoes and agitators is such as to direct it to the outer edge of the pan, where it again mingles with the quicksilver in the groove or channel, *R*. The pulp is then directed by the inclined or beveled edge of the pan toward the upper edge of the pan, where it strikes the inwardly-projecting curved rim, *P*, which throws the heavier particles of pulp by centrifugal action toward the central groove, *N*, through the opening, *O*, where they may again mingle with the quicksilver. The lighter material may then pass off with the water, which is continuously overflowing all around the pan. In this way the pan is kept free by the ore passing off in the muddy water after it is ground sufficiently fine to float, and the ore is not ground and re-ground as in other pans.

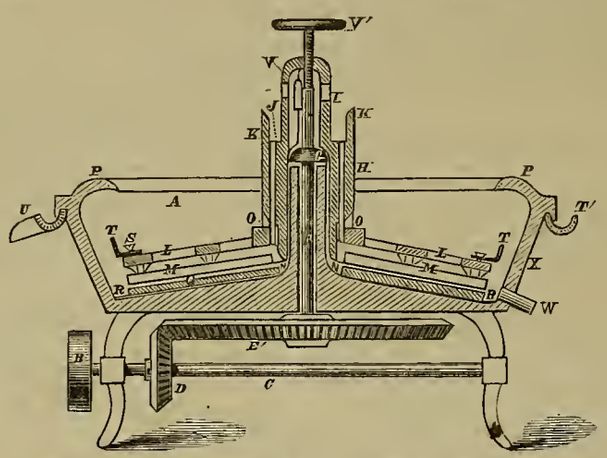

FIG. 1. MICHEL'S IMPROVED AMALGAMATING PAN.

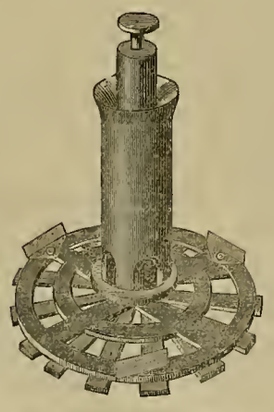

Fig. 2. Arrangement of Muller.

The grooves, *N* and *R*, are formed hy the dies or false hottoms as shown in Fig. 3, which are of the same dimensions as the shoes or grinders, and which do not cover the entire surface of the hottom, hut leave the channel around the outer edge and center of the pan as described. These grooves are filled with quicksilver, where it is held in one hody, instead of being ground with the pulp, as is the case with many ordinary pans. The quicksilver not being ground is not "floured" into fine particles which will pase off and be lost.

As a uniform motion of the water and pulp, while the pan is in operation is desirable, the adjustable agitators are added. When the shoes are new the desired velocity is obtained without the use of agitators; hut as the former wesr down, the position of the latter is changed so as to keep the motion of the water and pulp the same. Those desiring further particulars concerning the new pan may address Mr. Michel, the inventor, at the address before given.

AN APPOINTMENT FIT TO BE MADE.—Clarence King, on nomination of Presideut Hayes, has been confirmed by the Senate Director of the United States Geological Survey. This (and we say it without any purpose to disparage the claims of others to the position, if such were made,) is the right man in the right place. The former two surveys, the one under Dr. Hayden, and the other under Lieutenant Wheeler, having been consolidated, no more competent or deserving man could have been chosen for superintending the whole work than Mr. King. Dr. Hayden was, perhaps, equally well qualified for the place, but having opposed the consolidation, his aspiration to the position of General Director almost necessarily met with disappointment when this opposition failed of its object.

CALL FOR MORE METEOROLOGY.—The New York *Herald* calls for more frequent meteorological observations by the government for the protection of commerce and agriculture east and west. Instead of one set of observations limited to this continent, they should reach Europe and Asia. For an international system worthy of great countries we should have a daily exchange of observations through several centers—Washington, San Francisco, London or Paris, Berlin or Vienna, St. Petershurg, Rome, Constantinople or Cairo, Calcutta and Yokohama.

Fig. 3. Dies in Michel's Pan.

THE first importation of American meats into Germany some years ago resulted in failure. The last season 35,000,000 pounds were imported there of heef of the best quality, sown tightly in thick canvas,

Artificial Crystals of Gold.

We have received from Prof. Albert Chester, of Hamilton College, New York, two microscopic slides containing artificial crystals of gold, one prepared hy the battery process from a solution of the chloride, the other from an amalgam, the mecury of which is driven off by digesting with nitric acid instead of by heat. As is known to all experimenters, the form of the artificial crystals from a solution of the chloride, is a most beautiful and delicate feather or fern-leaf form, but those sent by Prof. Chester are the handsomest we have seen. He has been making microscopic observations of the points of difference hetween the natural and artificially produced crystals of gold, the results of which have been communicated to Eastern scientific journals. Briefly, it may be remarked that the crystalline forms observed upon hars of pure gold cast for dental use, are generally tringular and occasionally show several faces of the octohedron, but are never hexagonal, as is frequently the case with natural crystals. Nor do these bare show the dendritic forms so common in nature, and now easily obtained artificially by deposition from a solution.

Concerning the feather or arborescent forms obtained by the battery process, Prof. Chester has published interesting observations showing that the angle which the side ribs make with the mid-rih, is unvariably one of 60°, making an angle of 120° between the two sets of side ribs. Prof. Chester notes that it is very difficult to measure the angles in the case of these artificial crystals, because the mid-rib is usually more or less curved and the whole form presents great irregularities. However, he sought to prove the constancy of the 120° angle, hetween the two side ribs, by a long series of measurements. A series of 50 measurements of crystals taken at random, gave an average of 119° 85′, which is certainly a close approximation. On these crystals Prof. Chester also notes the extreme flatness of the feather-formed crystals, one of them being fully studied under a power of 300 diameters without a change of focus. This is unusual in crystals of isometric forms.

The second slide which we received shows the octohedrons obtained from an amalgam allowed to form on a surface of pure gold. If the amalgam is treated by heat, the mercury is driven off and the surface left amorphous or covered with angular depressions. Distinct but minute crystals of gold amalgam may be easily ohtained if the mercury is dissolved out with dilute nitric acid. A series of measurements on a numher of these crystals proves them to belong to the hexagonal system. The average of 48 measurements of the prismatic angle is 119° 53′, the six angles of the most perfect one measuring as follows: 120° 30′; 121° 6′; 119 12′; 119° 6′, 120° 36′ and 120° 12′. These crystals are often imperfect. The pyramidal planes are sometimes entirely wanting, the crystal having only a basal termination. The base is often hollow, and in one case was entirely gone. In the *American Journal of Microscopy* for January, 1879, Prof. Chester gives fuller detaile concerning the characteristics of these crystale and the methods hy which they are best attained. The study is of much interest to students of crystallography.

THE VISALIA DELTA is now published by Walker & Barnes, who recently purchased the office of E. M. Dewey. Mr. Dewey has spent some 10 years in active service as editor and publisher of the *Delta*, and succeeded boldly and independently in making it one of the most successful local weeklies in the State. We are fully acquainted with Mr. Walker, a sincere and reliable man, and efficient job printer, and understand that himself and partner are well calculated to maintain the efficiency and increase the popularity of the establishment. The office is one of the hest equipped in the interior of California.

THE coal industry of Pennsylvania has reached enormous proportions, the annual product heing valued at $50,000,000. The first coal mined, amounting to a few hundred tons, was sold in Philadelphia in 1813 for $21 a ton.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Nevada's Wealth.

A Great Salt Marsh.

EDITORS PRESS:—I did not complete my intended descriptions of the various matters of interest in my former letter, for fear of trespassing upon your columns, and yet your paper is devoted to the diffusion of knowledge and the publication of facts that pertain to the benefit of the whole country; and as I found the SCIENTIFIC PRESS in nearly every cabin I visited in the mines, I shall presume upon its columns to give the people outside of Nevada the facts concerning the dormant wealth that lies hidden amid the mountain ranges and marshes and valleys of that young State.

Among our explorations of the great salt marshes, one very remarkable curiosity attracted my attention, and that was the number of fresh water springs flowing up and spreading out over the surrounding ground, and in close proximity to the salt springs and not more than 100 feet from the large soda spring. The opening in the ground was circular in form and about two feet in diameter. We could look down into the clear, sparkling water for several feet and it apparently had no bottom. Nature seems to have been very lavish in her experiments at this point in regard to springs, for there certainly is not another such a combination of waters impregnated with so great a variety of mineral salts on the face of the globe. The terminal points seem to have centered in this basin from sources that are miles away, and horn in their subterrancan passages, each and every one keeping separate and distinct until they unite and mingle upon the surface, where each forms its own peculiar deposit.

The fresh water springs contained considerable carbonate of lime ($CaCo^2$), but was exceedingly fresh and pure and cold; and at no distant day will this spot be visited by the most scientific as an anomaly in nature worthy of their deepest thought and most vigorous research.

About three miles distant in the same valley, and quietly sleeping beneath the shadow of a lofty mountain, can he seen the famous hot springs, where the miners from the adjacent mining camps would often gather to boil their eggs (if they had any) or make themselves a hot cup of tea. Some one more enterprising than the rest, and having an eye to his sanitary conditiou, has erected a board shanty over one and arranged a sluice way for bathing purposes; and when the population of the State, or of this surrounding country especially, becomes sufficiently numerous, this will be a grand resort for bathing purposes. Then do not consider me extravagant in my expressions of wonder at this remarkable group of springs, as there are soda springs, horax springs, soft-water springs, limestone springs, salt springs, sulphur springs, iron springs, magnesia springs, bitter springs, and last, but not least, iodine springs—all within the radius of a few miles.

As there are over 2,000 springs, and each spring capable of producing from one to five tons each per day, it is easy to calculate the magnitudo of the amount of salt that this source could supply; and putting the gross yield at 3,000 tons per day (a low average), and the price at $20 per ton, delivered in your city, would make an aggregate of $60,000 per day, or $18,000,000 per annum for 300 working days. And as the flow of brine is continuous, what an immense source of wealth this will be to the State, and as it is an amount over and above consumption, the effect upon the general prosperity of the State would he felt in every avenue of its prosperity. The only drawback at present is the want of a more expeditious way of getting it to market, and as a narrow-gauge railroad could he built from Wadsworth to the springs, a distance of 110 miles, for $600,000, it certainly cannot remain long in this unprofitable condition. Some of our enterprising capitalists will certainly step in and build a road, that they are assured will have 3,000 tons of freight one way and a large amount the other way.

I passed over the entire distance from Wadsworth to the springs, and can safely say that $300 per mile will do the grading, and the heaviest up-grade would not exceed 20 feet to the mile.

The investment would double itself every year after paying for running expenses, wear and tear, etc. I have not seen an enterprise on this coast that offers such an enormous remuneration for the investment.

The following facts have been collated from reliable sources upon the construction of a narrow-gauge railroad, and can he relied upon as coming within the range of the probable expense:

Road bed—54 tons 35-lb rails at $30	$1,620
Chains and spikes, per mile	210
Cross ties, per mile	800
Grading and track laying	1,000
Culverts and bridges	100
Superstructure	$3,730
$3,730 per mile, 110 miles	$410,300
8 engines, $7,500	60,000
6 passenger cars, $1,600	9,600
2 baggage cars, $1,200	2,400
150 freight cars, $800	124,000
Cost of operating	$606,300

The several narrow-gauge railroads of this country have demonstrated that they can he run for 30 cents per mile per train, which would make this exhibit:

110 miles—one train each way making 220 miles at 30 cents	$ 66.00
Wear and tear, 2½%	35.00
Interest on $600,000 at 1%	233.30
Cost per day	$334.30
Receipt from 3,000 tons of salt one way, at $2.50 per ton	$7,500.00
50 tons out-bound at $10	500.00
Passengers and miscellaneous	250.00
	$8,250.00
$8,250.00 per day less $334.30=	$7,915.70

Seven thousand nine hundred and fifteen dollars and seventy cents per day, for 300 days, would give us a surplus upon the investment of $2,374,710, or four times the coast of the road every year.

I will add as a contingent, to cover any discrepancy, $100,000 for additional motive power and cars, and then there is no railroad project on the continent that will pay so large a dividend as this little road. And yet I have not mentioned the thousands of tone of ore that would he shipped to your city for treatment, if it could he got there at a reasonable cost. I saw in one dump over 10,000 tone of ore, that will pay, at least, $100 per ton, that would he shipped at once if there were railroad facilities; and ledges varying from 10 to 40 feet, that will supply thousands of tons more the moment transportation facilities were completed, if they did not conclude to erect mills.

The scarcity of water is the great drawback to the erection of mills at the mines, and as wagon transportation is so expensive through those barren sand wastes, owners of mines would at once avail themselves of railroad transportation, and your city would reap a harvest in the interest that would at once spring up in the establishment of large metallurgical works, and the State would be largely benefited by the further development of these vast bodies of mineral deposits.

It has been demonstrated that no link in the whole chain of general prosperity brings such certain and lasting benefits as the iron rails of railroads, and there is no place in the country where this accomplishment would bring a more certain reward than a railroad connecting Esmeralda county, Nevada, with the Central Pacific, at some convenient point of connection.

JNO.

Steam Threshing Engineers.

EDITORS PRESS:—By giving some attention to the steam boiler question, particularly boilers used for threshing purposes, you will be instrumental in saving many valuable lives. There is not a season passes but what there are three or four, or more, explosions, and from six to a dozen lives lost, and the threshing season only lasts from three to four months on the average. Is this sacrifice of life and property necessary? It appears to me that two-thirds, if not three-fourths of these accidents could he avoided by having careful and experienced hands.

Examine those explosions that happened last summer. One man who knew comparatively nothing of an engine, exploded his, killing himself and scalding his father. Another young man was so flustrated by the water-glass breaking that he was incapacitated to run, and the result was an explosion; probably as soon as the water got below the crown sheet. This young man was a practical illustration of theory without practice, and paid his life for the experience, besides scalding others. He had served an apprenticeship, but be it understood that all machinists are not engineers. A third case was an Ames straw-burning boiler. The number of lives lost I am not aware of, though there were more wounded than in either of the other cases. When the first Ames straw burners were built, the main flue was of too light iron and not braced. The heads had two three-quarter braces or etays eight feet long. They would have been safe at from 50 to 60 pounds of steam, but were run at from 110 to 135 and 140 pounds. Sane men could not expect them to last more than two or three seasons without bursting under such a pressure.

The sad affair at Stockton was doubtless the result of carelessness. A careful man would know at what pressure his safety valve would blow off at, and keep his steam just so that it would not blow off; especially if his gauge was out of order. The blow off point should not he more than five or ten pounds above what you run at; and running over 100 pounds is dangerous, and straining to most boilers.

To show how a careful engineer is rated by some less scrupulous in the business, I will cite a case that happened in Sacramento county last summer. The engine under consideration was a No. 4 Ames straw burner, return flue. The end of the flue was badly burned and rusted; the rivets holding it to the flue sheet nearly burned off on the sides, and the tubes almost constantly leaking. When four cracks in the end of the flue and flange of the flue sheet appeared in one week, two in one day, the engineer gave notice that he would quit, as soon as a substitute could be found, if it was not repaired. He was discharged; the man taking his place declaring that there was no danger so long as there was plenty of water. They ran one and a half days, when temporary repairs were made. The boiler is now receiving thorough repairs, to the credit of the owners.

A locomotive engineer is proven before he gets an engine, and a steam-boat engineer has to get a certificate; why should others be exempt? The pay is generally sufficient to secure competent hands, if due caution is used in hiring them. Cities drive powder magazines to a distance, but allow boys and other irresponsible persons to have charge of boilers in their midst, thereby jeopardizing life and property by simple negligence.

Farmers, see that the machine that threshes for you has a competent and careful engineer, for you are liable to your neighbors for damages if a fire, through carelessness, damaging them starts on your place. Blow ups make fires.

A READER.

Routiers, Sacramento Co.

The California Game Laws.

SECTION 1.—Section six hundred and twenty-six of the Penal Code is hereby amended so as to read as follows:

Section 626.—Every person who, in the counties of San Bernardino or Los Angeles, between the first day of April of any year and the first day of August of the same year, or who, in any other of the counties of this State, except the counties of Lassen, Plumas and Sierra, between the fifteenth day of March and the fifteenth day of September in each year, hunts, pursues, takes, kills, or destroys quail, partridge, or grouse, mallard, wood, or summer duck, red-head gadwell, or gray duck, or blue-winged teal, is guilty of a misdemeanor.

Every person who in the county of San Joaquin, between the first day of January and the first day of July, in each year, hunts, pursues, takes, kills or destroye doves, is guilty of misdemeanor.

Every person who, at any time, takes, gathers or destroys the eggs of any mallard, wood, or summer duck, red-head, teal, gadwell, or gray duck, or any other species of wild duck is guilty of a misdemeanor.

Every person who shall have any of the aforesaid game in his possession at a time when it is unlawful to kill the game, is guilty of misdemeanor.

SEC. 2. Section six hundred and twenty-eight of said Code is hereby amended so as to read as follows:

Section 628. Every person who, between the first day of November in each year and the first day of July of the following year, hunts, pursues, takes, kills or destroys any male deer or buck, shall be guilty of a misdemeanor.

Every person who shall, for the period of four years from and after the passage of this Act, pursue, hunt, take, kill or destroy any antelope, elk, or mountain sheep, or female deer or doe, shall be guilty of a misdemeanor.

Every person who, after the passage of this Act, shall kill any spotted fawn, shall he guilty of a misdemeanor.

Every person who, after the passage of this Act, shall take, kill or destroy any of the animals mentioned in this section, at any time, unless the carcass of such animal is used or preserved by the person slaying it, or is sold for food, is guilty of a misdemeanor.

SEC. 3. Section six hundred and thirty-three of said Code is hereby amended so as to read as follows:

Section 633. Every person who takes, catches, or kills any speckled trout, brook or salmon trout, or any variety of trout, between the first day of November and the first day of April in the following year, is guilty of a misdemeanor.

SEC. 4. Section six hundred and thirty-four of the Penal Code is hereby amended so as to read as follows:

Section 634. Every person who, between the first day of August and the fifteenth day of September of each year, takes or catches, buys, sells, or has in his possession any fresh salmon, is guilty of a misdemeanor.

Every person who shall set or draw, or shall assist it setting or drawing any net or seine for the purpose of taking salmon in any of the waters of this State, at any time between sunrise of each Saturday, at twelve o'clock noon of the following Sunday, is guilty of a misdemeanor.

Every person who, between the first day of April and the thirty-first day of December in each year, takes or catches, buys, sells, or has in his possession any fresh shad, is guilty of a misdemeanor.

Nothing in this chapter shall be so construed as to prohibit any person from catching fish with hook and line at any time in the tide waters of this State.

SEC. 5. Section six hundred and thirty-six of said Code is hereby amended so as to read as follows:

Section 636. Every person who shall set, use, or continue, or who shall assist in setting, using, or continuing any pound, weir, set net, trap or other fixed or permanent contrivance for catching fish in the waters of any of the creeks, rivers, or sloughs of this State, is guilty of a misdemeanor.

Every person who shall draw, or who shall assist in drawing, any net or seine for the purpose of taking fish in any of the waters of this State, the meshes of which are less than one and one-fourth inches in size, is guilty of a misdemeanor; *provided*, that nets with a mesh of a smaller size may be used in the catching of shrimps.

Every person who shall cast, extend, or set any seine or net of any kind for the catching of fish in any river, stream, or slough of this State, which shall extend more than one-third across the width of said river, stream, or slough, at the time and place of such fishing, is guilty of misdemeanor.

Every person who, by seine or other means, shall catch any fish so small as to be able to escape through a mesh of one and a half inch in size, or the young of fish of any species, but which, at the time of capture, are too small to be marketed, and who shall not return the same to the water, immediately and alive, or who shall sell, or offer for sale, any such fish, fresh or dried, is guilty of a misdemeanor.

Every person convicted of violation of any of the provisions of this chapter shall he punished by fine of not less than fifty dollars, and not more than three hundred dollars, or imprisonment in the county jail of the county where the offense was committed, for not less than thirty days nor more than six months, or by both such fine and imprisonment.

One-half of all money collected for fines for violation of the provisions of this chapter shall be paid to informers, and one-half to the District-Attorney of the county in which the cass is prosecuted. All other costs shall be a charge against the county in which the action is prosecuted. Nothing in the chapter shall he construed to prohibit the United States Fish Commissioners, or the Fish Commissionere of the State of California, from taking such fish as they shall deem necessary for the purpose of artificial hatching nor at any time. All nets, seines, fishing-tackle, boats, or other implements used in catching or taking fish in violation of the provisions of this chapter, shall he forfeited, and may be seized by the peace officer of the county, or assistant, or person acting under the authority of the Fish Commissioners, and may be by them destroyed, or may be sold at public auction by the party making such seizure, upon notice posted in said county for five days. The person making such seizure and sale shall be entitled to retain one-half of the proceeds of such sale, and the balance shall be paid into the school fund of the county, in case the seizure and sale is made by a peace officer thereof, or to the Fish Commissioners if made by a person appointed by them; *provided*, that all nets having meshes of less than one and a half inches in size, when seized under the provisions of this section, must he destroyed.

SEC. 6. The Act shall take effect and be in force from and after its passage.

Santa Clara County Game Regulations.

An Act having passed at the last session of the Legislature for the protection of fish and game in the State, which was injurious to the people of their county, the Supervisors, at the April session, in accordance with power conferred upon them by Section 1,046 of the Political Code, made the following regulations for the protection of game and fish in Santa Clara county, which differs materially from the dates in the last State enactment. It is made a misdemeanor to take, kill, or destroy quail, partridge, or grouse between the 15th of March and the 15th of September each year. Elk, deer, or antelope must not be taken or killed between the 1st of December and the 1st of July of each year. It is made a misdemeanor to take or catch trout between the 15th of October and the 1st of April; it is also made a misdemeanor to take, catch, or kill trout at any time by the use of nets, weir-baskets, traps, drags, or any explosive agent.

Immigrant Sleeping Cars.

At their shops at Sacramento the railroad company is at present engaged in fitting up 25 cars, which are to be used for the transportation of immigrants and emigrants to and from the East, and which are a great improvement on those at present in use. The new cars are being fitted with upper and lower berths, somewhat after the manner of cahoose cars. The upper berths swing freely on iron rods, and when not in use can he hung up on the roof of the car, where it is not in the way. The lower berths are formed from the seats, which are made up after the manner of the present sleepers, by turning down the backs, etc. Slats are then placed crosswise, and when laid out the berths are exceedingly neat and comfortable. This will he a great convenience to persons traveling third-class, as heretofore they have been compelled to sit up or make shift the best they could. The only difference between these remodeled cars and the present sleeper will he that the former will not he upholstered. Another benefit which the Company will derive from this improvement is that they will be enabled to carry more passengers in a car, from the fact that heretofore only one passenger could he placed in a seat, so that he could have an opportunity to lie down, but now the upper berths will make sleeping room for an extra number and more can be accommodated. It is a merciful act on the part of the Company, as heretofore the immigrants and emigrants have been very uncomfortable while traveling. Several of the altered cars are already completed. —*Sacramento Bee.*

HOW ARTIST'S CANVAS IS PREPARED.—The raw canvas must be stretched on a frame, wetted, and restretched if loosened by wetting, and coated with a mixture of equal parts of dry whiting and white lead, ground up with raw and boiled linseed oil, and laid on with a trowel like a plasterer's trowel, but longer and thinner in the blade. If the canvas shows through the first coat, a second and a third may be applied, the under coats being rubbed down with pumice stone. A little raw umber may be added if a stone-colored surface is preferred.

MECHANICAL PROGRESS.

Economy of Clothing Boilers.

The following ars the results of somo experiments conducted ssveral years ago, at the Newport iron works, Middlesborough-on-Tees, Eng., to test the value of a good lagging—Jones's non-conducting cement. The boiler (vertical) was connected with a puddling furnace, and was not protected by a roof. It was worked at 50 pounds per square inch, and in the second experiment the whole of the shell, an area of about 280 square feet, was coated with the composition. During the experiments the weather was fine and warm, and the coal used, the iron produced, the time of the experiments, and all other circumstances, were exactly similar in the two cases. A water meter was attached to the feed-pipe, and this showed the exact amount of water evaporated with and without the covering. The results were as follows:

Boiler not Covered.

Total water vaporized per meter, Monday to Saturday, 11,690 gallons.

Total time, 126 hours = 92¾ gallons = 14.8 cubic feet per hour.

Boiler Covered.

Total water vaporized Monday to Saturday, 16,060 gallons.

Total time, 126 hours = 127.5 gallons = 20.4 cubic feet per hour = 5.6 cubic feet per hour more than when the boiler was uncovered, a difference which plainly shows the immense loss of heat under the latter circumstances.

Experiments by Jacob Perkins long ago proved that in case of pipes filled with steam at 100 pounds per square inch, 100 feet of surface exposed to the atmosphere is, under ordinary circumstances, sufficient to condense per hour the steam produced by the vaporization of a cubic foot of water.

Regarding this experiment *Engineering* says: "It will be seen that a square foot of ordinary heating surface has about one-fifth the heat-transmitting power of a square foot of freely exposed cooling surface; or supposing that in any given boiler the areas of heating and cooling surface are equal, the effect of the latter, if freely exposed, would be to reduce the evaporative efficiency of the boiler 20%.

The exposed surface of a boiler, or its cooling surface, in no way differs from its heating surface; it is subject to the same laws, and, under similar circumstances, would produce similar effects. That a square foot of cooling surface withdraws from the contents of the boiler a less amount of heat than is imparted to them by an equal area of heating surface, is merely due to there being a less difference between the temperature of the atmosphere and that of the contents of the boiler, than there is between the latter and temperature of the gases in the flues. Other circumstances being equal, the transmitting power of any given area of boiler surface varies directly as the difference in the temperature on the two sides of it, any increase in this difference enabling the surface to transmit a proportionately increased amount of heat in a given time.

WIRE BELTS.—We made some allusion a week or two since to the manufacture of wire belts. We now find the following additional, and more in detail, in the *Iron Age:* "Machine straps of wire, as a substitute for leather, are being made by a German firm. The belts are made of the best crucible steel wire, in transverse network of one to ten wires, in any desirable length or width. The two ends of the strap are joined like the middle, so that there is no beginning and no ending, the belt forming an endless band. All the wires run parallel only across the width, in such a manner that one wire catches into the other like a spiral, a continuous, densely-woven chain being thus produced, the movability of which is so great as to enable it to go round the smallest pulley. The straps are also made with leather or elastic lining, or bordered with leather, elastic, hemp, hair-tape, or any other material, also its interstices filled with gutta-percha, to supply elastic bands with cotton web, and to prevent their stretching. The tightening of the strap—shortening of the chain—which is only necessary once, viz., when put on by means of a strap key, may be effected very easily and very quickly by taking out any desirable number of wires, and again joining the two ends in the same manner by twisting in the required number of wires."

A REMARKABLE case of cohesion, or the welding of two metals at a temperature far below the melting point of either of them, has lately been noticed by Mr. Charles A. Fawsett, of Glasgow, and by him reported to Sir William Thomson. He describes the following experiment, which any of our readers who are curious enough can readily try, to test its correctness: If a piece of silver, one centimeter square, is heated on the inverted lid of a porcelain crucible, to about the temperature of 500° C. (932° Fahr.), and the end of a thin platinum wire is brought into contact with it, the two metals will be found to have welded to that extent that the silver may be raised from the lid, and will remain attached to the platinum wire when cooled off. Mr. Fawsett reports that other metals—copper and aluminum, for example—will likewise adhere to silver, though the experiment is less striking than in the case of platinum.

Balanced Slide Valves.

Many curious attempts have been made within the scope of scientific invention to solve the problem of "balancing" slide valves. Inventors, inspired with a consuming ambition to devise something which could be entitled a "balanced slide valve," have really, with mental centrifugal force, thrust upon a suffering community much in this line, which, instead of answering the purpose intended, has only gone to convince the public of the unbalanced condition of their mental equipoise. We do not intend this as a reflection upon inventive talent, nor to divert such talent from its true course, but rather as a kind of admonition that misdirected mechanical genius finds little favor in the eyes of a tolerant public. We have really seen a "balanced" slide valve so thoroughly balanced that it was impossible to keep it upon its seat when subjected to steam-pressure; and yet the inventor claimed all kinds of imaginary savings for this really peculiar device.

Another "balanced" valve consisted of an ordinary side valve, to the back of which, and at right angles to its face, was attached a circular piston, equal in area to the face of the valve. The valve, when in motion, "rods" upon the end of the piston rod, which terminated in a plate traveling in a groove on the back of the valve. Here was simply a case of transferring the friction from the face of the valve to its back, with the odds in favor of an increase rather than a decrease of friction. Yet this mechanical creation revelled in the title of a "balanced slide valve." Thus far the ruling idea with inventors has been that, in order to balance a slide valve, it is necessary either to exclude the action of the steam from the back of the valve, or else to admit the steam pressure upon the back and face of the valve simultaneously. The possibility of constructing a hollow valve, and balancing it by internal pressure of steam, seems to have been ignored altogether. It is hardly a wonder that so many unsuccessful attempts have been made to accomplish a purpose so radically needed. It is many years since steam was introduced as a motive power, and yet to-day the means of converting its force into work are not very materially different from those employed in its pioneer usage. Steam engines are built day after day with some new-fangled, improved, or automatic cut-off valves, which in some cases do effect a saving of steam and thereby fuel, but in many more they do this even at an increase of friction necessitated by great increase of valve surface.

Little or no advance has been made in balancing the locomotive slide-valve. The pressure upon the ordinary locomotive valve amounts even to tons, yet few attempts have been made to lessen the enormous friction such pressure must entail. Some of our leading railroads have adopted friction rolls to overcome the great loss, the success of which, however, is questionable.

That a valve may be "balanced" *for a purpose,* it is necessary that it should embody the following conditions: 1st. It must "ride" upon its seat with the least possible friction. 2d. It must accomplish this without leakage, or "blowing." 3d. It must be so constructed that any wear upon its face or faces can easily be provided for. 4th. It must combine facility of inspection with durability of construction. 5th. Its form must not interfere with the expansive use of the steam; or, in other words, it must possess the feasibility of a "cut-off." 6th. It must be free from any unsteady or "wobbling" motion when the engine is running by its own momentum independently of steam pressure; this last is an item often overlooked in the construction of slide-valves, and which has frequently been the cause of much undue wear both upon valve faces and seats.—*Engineering and Mining Journal.*

To Prevent Explosion.

Mr. John Napier of Edinburg, Scotland, proposes the following mechanical device for the prevention of boiler explosions: The device consists in the attachment to the boiler of a plate of copper or other metal of similar qualities and ductility, which plate is firmly secured between two perforated plates of iron or other metal, and is covered by them on its upper and lower sides, except at the places of perforation, these places corresponding to each other in the upper and lower plates. The perforations are greater or less in diameter, according to the size of the boiler. Direct communication is established between the apparatus and the interior of the boiler, and according as the thickness of the intermediate plate is varied with reference to the strength of the boiler, it resists a greater or less pressure. When this pressure is exceeded, the steam causes the intermediate plate to give way at one or more points between the corresponding perforations of the upper and under plates, and by the steam thus escaping from the boiler an explosion is prevented. The apparatus, which is intended to be accessory to the ordinary safety valve, may be either attached to the boiler or fitted to a tube or neck secured to the boiler. In order to give additional security, the apparatus may be fitted in two or more places on the boiler subjected to pressure. The plates are so attached to the boiler and to each other that the intermediate plate may be readily removed and replaced by a fresh one.

SCIENTIFIC PROGRESS.

Light and Life.

The question as to how life is affected by the different colors of the spectrum has at various times engaged attention, and plant life has apparently been more studied in this respect than animal. Two distinct series of researches lately described to the French Academy seem to afford some fresh insight into the matter, and it is interesting to compare them together.

One series, by M. Bert, was on plants; the other, by M. Yung, on the eggs of certain animals. M. Bert kept plants within a glass trough inclosure, containing an alcoholic solution of chlorophyl (very frequently renewed), and exposed them thus in a good diffuse light. The solution, which was very weak, and in a very thin layer, intercepted little more than the characteristic region of the red in the spectrum. This excluded part, then, was proved to be the indispensable part of white light, for the plants immediately ceased to grow, and before long died. It is in this red region (as M. Timirizgeff has lately shown) that the greatest reduction of carbonic acid takes place. If red rays are kept from the leaf the plant can no longer increase its weight, it is reduced to consuming reserves previously accumulated, exhausts itself, and dies.

This part of the spectrum, however, though necessary, is not sufficient. Behind red glass plants may no doubt live long, but they get excessively elongated and slender, and their leaves become narrow and little colored. This is owing to the absence of the blue violet rays. Thus each region of the spectrum contains parts that play an active *role* in the life of plants.

Now turn to animals. M. Yung has experimented during three years on the effect of different spectral colors on the development of the eggs of frogs (the common frog and the edible frog), of trout, and of fresh-water snails. It was found that violet light favored the development very remarkably; blue light comes next in this respect, and is followed by yellow light and white light (which two gave nearly similar effects). On the other hand, red and green appear to be positively injurious, for it was found impossible to get complete development of the eggs in these colors. Darkness does not prevent development, but contrary to what some have affirmed, retards it. Tadpoles of the same size, and subjected to the same physical conditions previous to experiment, died more quickly of inanition when deprived of food in violet and blue rays than in the others.—*London Times.*

EFFECT OF ELECTRICITY ON VEGETABLE GROWTH.—During last summer, Pasteur, according to *Comptes Rendus,* made some interesting experiments on the effect of electricity on vegetable and fruit growths. On the 4th of August, he enclosed some vine-sets in hot-beds, almost hermetically sealed. The grapes ripened about October 10th. Grapes that had ripened in the open air fermented in less than 48 hours, in a temperature varying between 25° and 30° (77° to 86° F.), but those that ripened under glass remained unchanged. This result, which had been predicted by Pasteur, lends strong confirmation to his views. Again, on July 30th, 1877, M. Celi planted three kernels of maize under each of two bell-glasses. The weight of the kernels, the kind of earth, and the quantity of water supplied daily, were equalized as nearly as possible. On August 1st, the kernels sprouted. During two days the growth was nearly the same under both glasses. On the third day the plants in electrized air began to develop more rapidly than the other. On August 10th, the following measurements were taken, from the base of the stalk to the extremity of the upper leaves: Plants in electrized air, 17 cm. (6.69 in.); plants in ordinary air, 8 cm. (3.15 in.).

MAGNETISM OF LOADSTONE AND OF STEEL.—Dr. A. L. Holz, a French scientists has investigated the comparative influences of equal amounts of magnetism upon the loadstone and upon glass-hardened steel. He has reached some novel conclusions, among which are the following: 1. The maximum of permanent magnetism in the loadstone, for equal volumes, is about the same as that in the hard steel. 2. The specific magnetism of the loadstone is the greatest of all magnetic bodies yet investigated. 3. The permanent magnetism of the loadstone is sooner reached than that of steel. 4. The quantity of temporary magnetism which disappears, after the magnetizing force is removed, is less in the loadstone than in steel.

ELECTRICITY OF CHEMICAL PROCESSES.—F. Braun finds that the percentage of potential energy convertible into mechanical work, varies inversely with the electric tension; a sudden change in the density of free electricity must be accompanied by a development of heat even if it is not followed by any change of relative distribution; if induction-currents in a spiral excite a maximum of free electricity, half of the work is converted into heat; in currents of small intensity, if a new current is added, a greater development of heat and a less degree of polarization arise when the new current is in the same direction as the original current than when the directions are opposite.—*Annals. of Physics and Chem. (German.)*

INTERESTING EXPERIMENTS IN REGARD TO SPONTANEOUS COMBUSTION.—E. Bing, of Riga, has experimented with different materials; wadding, raw flax, hemp, the waste from silk, wool and cotton spinning as well as sponge, and finally wood dust as found in any cabinet-maker's shop. They saturated with various fluids, viz., oils, fresh and in a gummy state; turpentine, petroleum, various varnishes, etc. All the fibrous materials took fire when saturated with any of these oils or with mixtures of the same. Sponge and wood dust, on the contrary, proved to be entirely harmless. Combustion ensued most rapidly with 17 grains of wadding and 67 grains of a strong oil varnish, in 37 minutes; while 200 grains of washed cotton waste, of which a portion was saturated with 750 grains of strong oil varnish and the remainder wrapped about it, required almost 14 hours. These materials were placed in a well-sheltered spot and subjected to a heat of from 18° to 40° C. Silk did not flame up, but slowly charred. Small quantities seem to take fire sooner than large.

THE MINERAL CERITE. — Although it was known for some time that cerium anilins black was a valuable color, it was not used in calico printing because it was thought that the cerium salts were too expensive, and no attempts to produce them cheaply were made. Recently, however, the manufacture of cerium anilino black has been introduced by Jacob Lytsche, of St. Petersburg, Russia, with much success. It was found that cerium salts sufficiently free from any injurious substances could be manufactured from the mineral cerite by a simple and cheap process which every calico-printer could easily carry out. At St. Petersburg the mineral which is derived from deposits in gneiss, near Riddarhytta, Westmannland, Sweden, is finely powdered, then treated repeatedly with sulphuric acid, and finally extracted with cold water. The cerium aniline black thus made is said to be cheaper and more effective than the vonadium aniline black.

IRON AND SILICON.—Some time ago there was taken from the ground, we forget in what locality, a metallic ingot having the look of iron, but, notwithstanding its long contact with moisture, showing no trace of oxidation. Prof J. Lawrence Smith, who lately analyzed it, found it to be a silicide of iron, containing 17% of silicide. This compound is so inalterable that it will remain without change in nitric acid of 1.40 density, or in bromine. Hydrochloric acid affects it somewhat. The history of the ingot is not known, but it is thought to owe its existence to some accident in the manufacture of iron. M. Daubree, commenting on this in the French Academy, stated that, notwithstanding every effort, it had not been found possible to incorporate more than eight per cent. of silicon with iron. M. Saint-Claire Deville was struck with the analogy of the product in question to the silicide of manganese produced some years ago by M. Brunner.—*Journal of Chemistry.*

CHANGES OF SPECTRA.—If a small quantity of mercury is placed in a hydrogen Geissler tube, E. Wiedeman finds that an inductive current gives the hydrogen spectrum at ordinary temperature. But if the tube is warmed in an air-bath, as the temperature rises the mercury lines appear, while the hydrogen lines grow fainter and finally disappear. If a tube of hydrogen and nitrogen is warmed at any point, so as to free sodium or other metals from the glass, the hydrogen and nitrogen lines vanish almost entirely while the lines of the metal appear. Does the hydrogen disappear, or is it transmuted into some other substance?—*Comptes Rendus.*

ALLOTROPY OF METALS.—M. Schutzenberger, in his investigations of the different molecular states of metals, finds that other metals than antimony, especially copper, lead and silver, take allotropic forms when precipitated from saline solutions, by electrolysis or otherwise. He predicts that this will prove to be the case with a large majority of metals. The less active and more stable modification is formed at the expense of the other, with loss of heat, like red phosphorus from ordinary phosphorus, or oxigen from ozone. Allotropic copper, when oxidizing in the air, takes brilliant rainbow hues, which may have a valuable industrial application.

SNOW ILLUMINATION.—During a recent snow-storm, in the early afternoon, an interesting experiment was tried in Paris. At the moment when the sky was darkened by snow, the electric lamps were lighted in the square of the Theatre Francaie. The reflection of the light from the snow-flakes immediately dispelled the darkness and produced a very pleasing effect. It is proposed to try a similar experiment in misty weather, and if the light can penetrate even to the distance of 20 meters (65.6 feet), Jahlochkoff lamps will be established at points where the passing is most frequent.—*Les Mondes.*

ELECTRO-CHEMICAL ACTION UNDER PRESSURE.—In a series of about 50 experiments, each of which continued for several hours, and during which pressures of 100, 200, 300, etc., atmospheres were maintained, A. Bouvet found the following laws: 1. The decomposition of water by a current is independent of its pressure. 2. The quantity of electricity necessary to decompose a given weight of water is sensibly the same, whatever may be the pressure. The laws are in perfect accordance with the mechanical theory of heat.

Mining Share Market.

The stock manipulators have allowed mining stocks to decline of late, till a decided panic has taken place. Thero was nothing from tho mines to warrant this beyond the fact that no immediate benefit could be made to accruo to tho Comstocks from the Sutro Tunnel compromiso. However, this was largoly used as an excuse, together with the expected disastrous effects of the new Constitution on stock operations, if adopted next May. Theso are, to great extent, mere pretexts. The present break did not come without assistance, and that assistance, beyond a douht, was furnished by the insiders to force the marginal stock npon tho market. This stock was finally squeezed out and immediately absorbed by somebody, which is enough to warrant the opiuion that the break was forced for this purpose, and perhaps the passago of these shares from weaker into stronger hands will open up the way to a more active and advancing market. Tho shrinkage is more severe than any folt since last Octoher. Any one familiar with the history of stock deals will remember that for a number of years past there has been a depression in the market at ahout this time, the one a year ago being peculiarly heavy. They all may be attributed to the same cause, viz., that people early in the year buy stocks at inflated prices in expectation of a "spring rise" or sometbing else, and as a result get the benefit of a fall. The present panic is peculiar, in that stocks have not for some time back heen running at fancy or inflated prices. Toward tbe close a slightly better tone prevailed, operators feeling that the marginal stocks being disposed of, tbey were better able to strengthen and enliven the market. Bodie stocks generally held their own—perbaps because they had their crash at the end of last week. All otbers, almost, fell and can scarcely as yet be said to have revived.

The Bequette System of Milling.

A plan for flour milling, dovised by Mr. D. Beqnette, and which has been styled a "mill without walls," owing to its peculiar style of construction, seems now in a fair way to be practically tested. Mr. Bequette builds a mill something on the pyramidal style, each story being smaller than the one beneatb it, thus gaining strength, solidity, capacity and altitude where they aro most needed. He groups his machinery around the center of tbe building, from story to story, in a way to secure great economy of power at a low cost for building and other outlays. His project is advanced as a great benefit to the State, by enahling its farmers and merchants to export flour, instead of wbeat, thus giving employment to a great number of people in the manufacture of flour, and cases to contain it, leaving the bran and offal to be used by otber branches of industry or production, and saving the freight on exports of waste material and the cost of imported grain hags, which would collectively effect a saving of several millions of dollars annually to the producers and consumers of breadstuffs. It is claimed that a Bequette mill would enable its proprietors to handle large quantities of grain, and produce a superior article of flour, at less cost than mills built upon the old and imperfect metbods, while such a mill would cost mnch less tban one of the present style of half its working capacity.

In order to test tbis system practically, an incorporation consisting of practical millers has been formed, and styled the "Cosmopolitan Milling Company," with offices at 712 Sansome street. The proposition is to erect a mill immediately, providing enough funds are subscribed. The experiment will be watched with interest to discover what measure of success it may attain.

Columbia River Bar.—The channel at the month of the Colnmbia river is said to be changing. It is tbe opinion of Col. Gillispie and others versed in such matters who have observed tbe movement of the bars that in a few years at most tbe main cbannal will be between Sand island and what is known as the middle sands. The bar across tbis channel is gradually washing out, and light draft coasters now occasionally come in that way, the water being 13 feet at low tide. The channel is true west from Chinook Point, and is almost straight from the southernmost point of Sand island. Should the depth become great enough in this new channel, the terrors of the Columhia river bar will have almost entirely disappeared. — *Crescent City Courier.*

Exhibits for the Australian Exhibition.

We have received a circular from Messrs. Edward Clarke & Co., 434 California St., S. F., inviting exhibits from this coast to the coming international exbibition at Sydney. Messrs. Clarke & Co., are authorized to receive the same.

Emigration continues to pour tbrough Burlington, Iowa, westward bound. These emigrants are mostly American farmers who expect to settle on new lands of Kansas, Nebraska and southern Colorado.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Volcano Notes.—Cor. *Ledger*, Mar. 22: T. Atkinson has opened a new claim in the Boulder Flat range. Baker, who bought the John Green claim, is running it night and day, and has a good clean-up in prospect. The Grass Valley claim, is tearing away at a furious rate. China hill, Union flat, Indian gulch and Grizzly hill, are all sending their quota of slickings to enrich the valleys. Moyle's hoisting works in the flat, have been delayed some on account of too much water in the ground. It was impossible for the Cornish pumps to keep it down in the pit so the men could work. J. Greisbanch will finish a crushing of 100 tons at the Mace mill this week, that will average $50 per ton, and has 80 tons on the dump at the mine that will pay $70. The Santa Cruz company have taken out some fine ore, and intend testing it at a mill soon. The only one in the vicinity—Stewart's mill—is kept constantly running on the Downs rock. Jones & Robinson have a fine lot of ore on their dump, with a good prospect of keeping it there, unless some enterprising man will come this way and build a small custom mill.

Plymouth Items.—The contract for sinking in the John mine is nearly finished. The shaft is 50 ft deep, and fine looking ore lies on the dump. The south extension is also being worked by other parties, with flattering prospects. The crushing of rock from the Victoria surrendered only $1.90 per ton. Charles Green & Co., have bought the north extension of the Illinois claim, from a man named Figgs. The Pioneer, owned by John Evans, adjoins the New London claim, south of Plymouth. The bottom of the shaft is covered with a strata of good ore, and the prospects for a paying mine is cheering. Negotiations are progressing for the disposal of the property. A company from below is expected to take hold.

CALAVERAS.

Gravel Mines.—*Chronicle*, Mar. 22: Brown & Co., tunnel claim, are working steadily, although not evincing a disposition to crowd things to extremities. They have one of the best claims in this section of the country. At present operations are confined to running a single drift necessary for the full development of the mine. At the Rough Diamond there is no particular change noticeable. The mill is not run steadily, the force of hands employed being unable to mine gravel as fast as the stamps can crush it. The Hoey & Sliter mine, in Old Woman's gulch, is in full blast again, having been bonded to a San Francisco company. Various improvements have been made about the mine, and the work of taking out gravel has commenced. Moser & Co., proprietors of the Bonanza hydraulic, are washing a vast deal of gravel. They are "wearing out" Tunnel ridge with rapidity. No clean-up has been made in the Bonanza this season, but the gravel looks and prospects first-rate. A partial clean-up is to be made next week.

EL DORADO.

Kelsey Mines.—Cor. *Democrat*, Mar. 22: The Gold Deposit will start immediately and the Robinson process for rebellious ores will be thoroughly tested. The Rosecranz mine has changed owners, and the work of putting it in running order will commence in a few days. The Estrella will probably start in a short time.

INYO.

Mining Notes.—*Independent*, Mar. 22: The Golden Star, owned by Cartier & Co., has a shaft 65 ft deep. The vein is an unbroken one of fine, gold-bearing quartz, with well-defined, good walls, and 20 inches wide at the bottom. The ore assays from $50 up to $5,000 per ton. Samples taken from the bottom show lumps of fine gold weighing from two to five grains each. The Eureka, a 30-ft shaft, shows a permanent ledge, carrying plenty of fine, free gold. Messrs. Woolsey & Phillips has some splendid prospects for valuable silver and lead mines, among which are the Woolsey ledge, the Burlington, Moscow, Chalfant, and others. One carefully selected sample from the Burlington gave the extraordinary assay of 1,920.91 ounces of silver, valued at $2,488.54. Others assay from $60 to $200 per ton in silver, and average 60% of lead. The Manhattan, owned by A. W. Eibeshuiz, has been opened so far by a shaft 67 ft in depth. Two samples of the ore assay as follows: First, silver, $116.23 per ton, 64% of lead; second, silver, $197.20, and 55% lead. Since the 1st inst. the Union Con. furnace at Cerro Gordo has been running steadily, putting through 20 tons of ore per day, the largest possible proportion of which is silver or San Felipe ore. The new works are yielding about nine tons per day of lead ore, and as the furnace started up with 300 tons on baud there is no reason why the run should not be continuous. One of the Hanger locations is a solid 16-inch vein of splendid gray carbonate metal paying well for shipment to and reduction in San Francisco. At depths of 100 ft the Beveridge District mines (across the summit) of Messrs. Porter, Hughes & Co., show gold ledges of increased strength and richness. The 30-stamp Brown Monster mill is running steadily on the low-grade gold and silver ores of the mine. Messrs. McKnight & Tully, of Virginia City, making their headquarters at the Shepherd place, have been for some time working mines directly opposite George's creek, with fine bodies of mineral, and important operations in the near future are indicated.

MARIPOSA.

Coultervile Mines.—Cor. *Gazette*, Mar. 22: The Martin & Nallin mine is not working at present, for the reason there is some 500 tons of high-grade quartz on the dump and no mill to work it. A new steam mill will be built close to the mine this coming summer, thus saving the expense of packing the ore some two miles on mules to get it to Hasloe mill. Mr. James Shimer has bonded the Bondurant to Mr. Bacon and others, of San Francisco. They intend to commence putting up hoisting and pumping machinery immediately, and then sink a working shaft to a considerable depth, run levels and put the mine in shape for working systematically. The ore carries a large percentage of sulphurets of galena and iron that has assayed as high as $4,000 per ton. The Eureka and Merced mines are turning out splendid ore; running the water-power arastra on ore from the former mine, which is paying $100 per ton. The ore is heavily charged with sulphurets of galena, zincblende, iron and a small percentage of telluride of tellurium. A short time ago a crushing of a few tons from the Merced paid $18 per ton. The ore is decomposed, and as the vein matter is from one to two ft in width, it is very easily mined and arastraed. Both mines are worked by tunnels, and can be to a depth of 1,000 ft or more. The General Ord mine is owned by Longhurst, May, and Allen. They are running a tunnel on the vein, which is in about 90 ft. At this point the vein is two ft in width, showing plenty of freed gold and a large percentage of sulphurets of galena, zincblende, and iron. They have a good water power right at the mouth of their tunnel, and contemplate building a five-stamp mill this coming summer. The Compromise mine, owned by Mr. A. G. Black, is not working at present, for the reason that there is a large amount of ore on the dump and no mill to work it with. Deepest shaft on the vein, 100 ft; width of vein, two to three ft; pay ebute fully 400 ft in length, with dyke crossings, one of the best indications there is of a permanent and lasting mine. The ore is of high grade, carrying a large percentage of sulphurete of galena and iron, which is worth $900 per ton.

MONO.

Dudley.—*Standard*, Mar. 24: The main west crosscut, 300 level, is in 257 ft. No particular change in ground since last report. The north drift is in 124 ft, and the south drift 85 ft. There has] been a great improvement in the vein in both of these drifts. An upraise is about to be started to connect the 300 level with the old workings, and the rich ore body there developed. This will serve the purpose of an air shaft, and at the same time will be used as an ore chute for taking out the ore.

Blackhawk.—During the week the shaft was sunk six ft; total depth, 320 ft. The bottom of the shaft is still in vein formation A station has been cut out and crosscuts have been started both east and west. The west crossent is in 11 ft, showing some quartz diffused through the rock. The south drift on the Warren vein was advanced seven ft; total length, 23 ft. The north drift is 10 ft in length. Total length of drift on the vein is 37 ft. In the face of the north drift the vein has narrowed slightly, but in the south it has widened. The character of the ore is about the same, and will average across the vein—four ft $65 per ton. The crosscut has advanced four ft during the week, making 11 ft on the west side of the Warren vein. It is expected that the outlying ledge will be cut at any time. The rock is still hard. An ore house and blacksmith shop is being built.

Belvidere. No change to notice in the west crosscut. A winze has been started on the Great Western vein at a point in the north drift, 200 level, 40 ft north from the main west crosscut, where some very good ore was found in drifting on that vein.

Standard.—The north drift from the main shaft, to connect with the incline is in 45 ft. The ledge is two and a half ft wide, and looks well. The south drift is in 270 ft; progress during the week, 14 ft. The ledge is three ft wide of good average ore. The ledge in the upraise in this drift four ft wide, and is looking very well. The north drift from the east crosscut, 300 level, is in 127 ft, showing a ledge 18 inches wide, of good ore. The north drift on the West Standard, 200 ft from the south line, which is down 10 ft, showing a ledge 18 inches wide, of very rich ore. The drift on the Cook ledge is in 200 ft from the south line. The ledge is two ft wide, of good average ore. The stopes are all looking well.

Bechtel.—On the 400 level, about 300 ft south of the shaft, a body of rich ore was drifted on, and the mine was thrown open to the public. The vein is as strong as any ever discovered in the district, and from present appearances it bids fair to continue to the south end of the Bechtel line, about 500 ft south of the end of the present drift. Ore is now being hauled to the Syndicate mill from this mine, and crushing will commence about March 25th. Stoping has been commenced and the drift will be pushed ahead with all possible dispatch. The Sitting Bull ledge is also looking very fine, and much ore of a high grade is exposed for stoping.

Tioga.—The work of excavating a station at the depth of 520 ft in the shaft is now in progress. Crosscuts both east and west will at once be started; also a lateral drift to be extended the full length of the mine. On the 420 level the east crosscut is now in 135 ft, with no important change to note. On the 320 level, north drift from the east crosscut is in 56 ft. The ledge is two ft wide, of good milling ore. This drift looks very promising. The west crosscut, same level, is in 245 ft.

Red Cloud Con.—The west crosscut, 400 level, is in a distance of 148 ft from the shaft. The formation at present indicates that the ledge will be found pitching west. The south drift on the Red Cloud ledge, same level, is in 37 ft. The ledge is 30 inches wide. On the 250 level a south drift has been started on the ledge cut in the west crosscut from the south drift on the Red Cloud vein. The ledge is 18 inches wide, and prospects about $16 per ton, in gold.

Bulwer.—The south drift, 380 level, is now in from the winze 116 ft. The ledge is two and a half ft wide, of good ore. The west crosscut from this drift is in 58 ft, and on the 15th inst. a very fine ledge was passed through, three ft wide. The ledge in the Stonewall stopee is looking well. The ore at the Bodie mill is turning out very well. Bar No. 2 has been shipped, valued at $16,506.08, and 600 ounces of bullion was carried over to the next melting.

MONTEREY.

Chualar Canyon Mines.—Salinas *Index*, Mar. 20: Mr. T. S. Baldwin is working and developing a mine in Chualar canyon. The lode runs nearly north and south, dips to the west, is 20 ft wide between the casings and has been traced for over two miles. The lode is now faced up the whole width to a perpendicular hight of 40 ft. A sample of the ore sent to San Francisco for assay, showed 22½ copper, $30 in silver to the ton, and $12 in gold. The copper is distributed throughout the entire width of the lode, and the gold and silver are found close to the casings, which are said to be largely composed of iron.

La Mines.—San Jose *Mercury*, Mar. 21: At present the company have one large bunker capable of holding 200 tons of coal, and the coal is loaded into vessels by means of a chute. The main tunnel is in 700 ft with two different branches leading off, both of which contain rich deposits of coal, and the work of taking out the coal is being pushed forward as fast as space will allow. All around on every hand can be seen coal, and there are as many as a dozen chutes, all of which had men at work sending the coal down into the cars, which are run out and emptied into the bunkers. The seam of coal varies from five to nine ft and is of good quality, comparing very favorably with the Wellington, and readily finds sale in the San Francisco market at $10 per ton, $12 per ton, while the screenings are sold from $3.50 to $5.

NEVADA.

Mining Notes.—*Foothill Tidings*, Mar. 22: The new mill of the Scadden Flat company is expected to be in readiness to commence dropping its stamps about the 1st of April. The tunnel of the Planet mine is in over 1,050 ft. A clean-up of 18 loads of rock has just been made at the Omaha mill, of ore from the New York Hill mine, which yielded $100 per load. Improvement is noted in size of ledge, quality of rock and general appearance. Extensive improvements are going on at the Spenceville copper mine. The Empire mine is reported as about to shut down. Within the last few months it has run several hundred dollars behind. A number of the miners have been discharged and the pumps taken up to No. Six. New Rocky Bar is about putting in a larger pump. Water has prevented much headway of late, but the mine looks well.

Watt Blue Gravel Mine.—*Transcript*, Mar. 22: The west drift is in 103 ft. The bedrock is granite and is raising very fast as they advance west. The bedrock has raised 12 ft in the whole distance. Everything is running as usual.

The Pittsburg.—There is no material change in the mine. The 600 north drift has been run a distance of ten ft. The lode in the latter drift presents well and is yielding good ore. The 500 north drift has been run six ft; this drift is also yielding good ore. All the stopes are producing well. The mill is running up to its capacity on company ore. All the machinery is doing finely.

NEVADA.

WASHOE DISTRICT.

Con. Virginia.—Gold Hill *News*, Mar. 26: The joint California winze from the 1950 level is down 90 ft, and averaging two ft per day through hard rock. A station is being cut out in the joint north drift from the west drift, 2150 level, for the purpose of starting an upraise to meet this winze.

Sierra Nevada.—The drift on the 2200 level connecting the east shaft and the incline, is now being graded and thoroughly timbered for a thoroughfare between the two points. The main incline is making usual progress through hard, brittle cap-rock nearly all of which is quartz, giving low assays. There has been a slight increase of water in the incline during the week, but not enough flows in to interfere materially with siuking. The bottom of the incline is to-day 92 ft below the 2300 level.

Julia Con.—The pumps are being worked carefully and are lowering the water slowly. The donkey pump at present is forcing the water through two miles of three-inch pipe besides raising it, as the pipe is not sufficient in size to convey off the water raised. The pipe being placed in the tunnel is six-inch. Through this the water will be forced by a pressure from the top of the tank of 20 ft, the pipe leading to the same being eight-inch.

California.—The C. & C. shaft is now 172 ft below the 2150 station, in hard blasting rock. The flow of water into the shaft from points above continues strong. The joint winze is making two ft per day through hard rock, and is down 90 ft. The usual repairs are being made to the joint drift, 1650 level, leading to the C. & C. shaft and to the Consolidated shaft below the 1400 level.

Union Con.—The joint Mexican winze from the 1600 level is adding three ft per day to its depth, and passing through hard blasting porphyry. It is now down 308 ft. The drift connecting with the Sierra Nevada on the 1465 level is still being repaired. The ventilation has been greatly increased by the connection between the Sierra Nevada and North Con. Virginia.

Belcher.—On the 2050 level the south drift is making five ft per day along the ore vein, and is in 383 ft. Fresh air has been conducted to the bottom of the incline by placing lining in so that the fresh air goes down on one side and the heated air up the other. The bottom of the incline is 170 ft below the 2500 station.

North Bonanza and Flowery.—The joint shaft is being sunk and timbered at the rate of 30 ft per week. It is following the east wall on down and is without increase of water. The pits for the new machinery have been completed, the anchorage put in, the anchor bolts placed and a couple of feet of foundation laid.

Mexican. The joint Ophir upraise from the 2100 level is making two ft per day, and is now up 46 ft. The joint winze is now 308 ft and continues in hard blasting porphyry. It is averaging three ft per day.

Ophir.—The joint Mexican upraise from the 2100 level to connect with the 2000 level is now up 46 ft and averaging two ft per day. The main incline is now 140 ft, on the slope, below the 2200 level, and is cutting birdseye porphyry containing stringers of quartz.

Justice.—The crosscuts west on the 1300 level continue to cut favorable looking vein matter carrying spots and seams of rich ore. The surface workings in the old Waller Defeat ground continue their yield.

North Con. Virginia.—The hot air coming from the Sierra Nevada up the shaft sometimes overcomes the men and makes the work slow, still it is making five ft per day. The new engine is ready to start as soon as the cables arrive.

Exchequer.—The north drift, 2400 level, is making four ft per day through soft vein porphyry, carrying streaks of quartz, and requiring to be closely timbered. Increased ventilation has been secured in this drift by putting larger air pipes in.

Gould & Curry.—Three shifts of nine men each are at work retimbering and repairing the old drain tunnel which was found to be very badly caved. The joint east drift on the 1700 level is averaging five ft per day through good working rock. At the Osbiston shaft the cutting out of a tank pit at the 400 level is completed.

Hale & Norcross.—The entire force employed is engaged in timbering and bracing the timbers in the 2000 east drift connecting with the Chollar-Norcross-Savage shaft, preparatory to allowing the water to raise and flow through this drift. The timbers in the incline have been strengthened and braced from the 1900 to the 2000 level, and the pump-rod stayed.

Ward.—The new engine is running to perfection. The shaft has been cleaned to the water's edge, and is being emptied out. On the 800 level the station is being enlarged to take in the south compartment of the shaft.

Lady Bryan.—The shaft below the 600 station is making good progress in bird's-eye porphyry. The west crosscut from the north drift has entered the quartz formation and is showing some very good rock. The east crosscut is in porphyry carrying large quantities of iron and stringers of quartz.

Chollar-Combination Shaft.—The house for the air compressor is finished and the boilers are set. The pumps are discharging over 100,000 gallons per day into the Sutro tunnel, holding the water below the 2200 station.

Utah.—Sinking the main incline was resumed Saturday evening, and it has now attained a depth of 350 ft on the slope below the 1350 station. The ground is good.

Overman.—The north lateral drift, 1600 level, is skirting the vein at the rate of six ft per day. Very hard rock and considerable water are encountered in the winze below this level.

Caledonia.—The east drift on the 1600 level is cutting very hard rock, rendering progress slow. The O & C shaft is averaging a set of timbers per day; total deptb, 530 ft.

Yellow Jacket.—Sinking below the 2280 level has been resumed and is now down 45 ft. The new compressor is in operation and works well.

Con. Imperial.—The drift north from the winze on the 2600 level is showing some most promising looking quartz, although skirting the vein.

Best & Belcher.—The joint east drift on the Curry line is in 667 ft from the lateral drift, and is making good progress in hard, dry rock. East crosscut No. 1, 1900 level, is averaging five ft per day in hard, blasting porphyry.

Alta.—The north drift, 1550 level, is still following the ledge in Benton ground and is making good progress. The joint winze below this level is being continued on down toward the 1750 level, where crosscuts are to be run at the same time that the vein, laid bare on the levels above, is opened up.

Leviathan.—The new cables for the vertical shaft having been received from San Francisco and put in running position, work is actively resumed in full at the 750 level. Both lateral drifts north and south are being pushed ahead actively, with excellent ore prospects in the face of both.

Savage.—General repairs are being made to the incline, but above the water level. The pumps hold the water below the 2000 level. Everything about the mine is ready for shutting down the pumps.

Crown Point.—The north drift, 2500 level, is being continued along the edge of the vein preparatory to running crosscuts to open up the formation. The usual work is being done in repairs.

Solid Silver.—Clearing out and retimbering the north end of the main tunnel or adit beyond the caved ground continues making good progress.

EUREKA DISTRICT.

The Eureka Con.—*Sentinel*, Mar. 24: Work has continued at the mine, and good progress made in the extension of drifts, etc., there having been 239 ft completed during the week. The ore bodies in the several levels are looking well and holding out well. The furnaces are running first-rate, having turned out 342 tons of bullion in the last seven days. The following work has been done: Fifth level—East drift from cave continued 50 ft, and is now in 278 ft; raise made, 14 ft, and is now up 66 ft. Seventh level—East drift from chute continued 17 ft, and is now in 211 ft. Eleventh level—West drift from ore chamber made 18 ft, and is now in 138 ft. Twelfth level—East drift continued 33 ft, and is now in 459 ft; south drift, east raise, continued 27 ft, and is now in 87 ft; south drift from west raise continued 30 ft, and is now in 86 ft. Thirteenth level—West drift continued 30 ft, and is now in 99 ft.

The Hamburg.—Interuediate drift advanced 18 ft, and is now within five ft of connecting with the upraise from the 450 level. The vein followed by this drift continues about the same. East crosscut, 450 level, has reached the shale hanging wall. Six hundred level—West crosscut advanced seven ft, a total of 123 ft. The rock has been very hard, but is now much softer in the face, and works well. The winze below the 600 level has been completed to the 700 level.

WHITE PINE DISTRICT.

Baldy Sour Mine.—*Sentinel*, Mar. 21: New York parties controlling the Baldy Sour mine, of White Pine, have telegraphed to their Superintendent to let contracts for a long drift from the 100 level of the Dawson mine. The interest being taken in White Pine mining property by Eastern capitalists argues well for an early resumption of active work on several mines of undoubted value situated on Treasure hill. A contract has already been let for drifting north from the same level in the same mine.

[Continued on page 204.]

Sanitary Influences of Trees.

[The following paper was read before the California Academy of Sciences, March 17th, 1879, by HON. B. B. REDDING.]

This subject has received but little consideration until within the past few yeare. It was rather from observation than as the result of direct experiment that it was ascertained that trees do exercise a marked influence upon the health of persons living in miasmatic districts. When this was noted, it seemed desirable, firet, to learn wherein air impregnated with miasma differed from the air over deserts that does not contain miasma; and secondly, to learn of what miasma consists. It must he confessed that the thousands of carefully conducted experiments by the ablest men, while tbey have resulted in adding vastly to the store of knowledge on cognate subjects, yet they have not satisfactorily answered these questions. De Saussure experimented on the quantity of carbonic acid in the air at Geneva; Verver, in Holland; Boussingault, in Paris; Roscoe, in Manchester; Schulze, at Rostock; and Von Pettenkofer and Wolffhugel, in Munich. Dr. Von Pettenkofer states that the variations in the result of these experiments, very small from the first, are found to be still smaller as the methods of determining carhonic acid bave been perfectcd. It is the same as regards the oxygen in the atmosphere. Dr. Von Pettenkofer caused air to he brought in hermetically eealed tubes from the desert of Sabara for the purposes of analysis, and adds, as the result of all his experiments, that the amount of oxygen and carhonic acid does not differ in air taken from the summit of Mt. Blanc, from deserts, from the swamps of Bengal, from cities, from forests, and from over the ocean. Dr. Mitchell says no analysis of malarious atmosphere has revealed any defect of its elements, or of its impouderahle constituents. Yet there is eomething generated in swamps and marshy land, in warm climates, that mingles with the air, which, when breathed or ahsorbed hy man and some other animals, is the cause of disease. Tbis something is called miasma.

What is Miasma?

Chemical analysis has heen unahle, as yet, to tell what it is. It does not even yield a hiut as to whether it is animal, vegetahle, or gaseous. The late Dr. John K. Mitchell, of Philadelphia, in a treatise on malarious fevers, gives the following various theories that have been held and advocated by physicians as to the nature of miasma. First, that it is a poison due to the decomposition of vegetable remains in low, wet places. Second, that the mephitic vapors of marshes only enfeeble health, and tbus enable the ohvious changes of heat and moisture to excite disease. Third, that all cases of periodical disease are due to seusible changes, and that the proximity of a marsh is only efficient as presenting an evaporating surface, hy which the air is made colder and damper. Fourth, that the morbid phenomena is due to the modification of the sensible and appreciable condition of the atmosphere. Fifth, lessened elasticity of the atmosphere. Sixth, particular gases generated by decaying vegetation. Seventh, the action of water on living vegetation; and eighth, the theory advocated hy Dr. Mitchell, and held hy that large class of eminent physicians who hold the proofs to he conclusive in favor of the germ theory as the cause of many diseases. They believe miasma to consist of the spores of a minute fungoid growth, which finds its home on moist decaying vegetation, and that these spores, when breathed and taken into the human eystem, are capable of subsequent multiplication, to the ohstruction of the vital functions. Dr. J. H. Salisbury, of Cleveland, Ohio, thinks he has discovered this microscopic fungus, which, he says, is one or more of the palmallæ. He has made a record of instances where he caueed earth, in which this microscopic plant was ripening, to he taken in hoxee and placed in the windows of the sleeping rooms of pereons residing in a non-malarious district. The air entering the cbamber was caused to pass over this earth. In from 10 to 15 days, the occupants of the chamber were attacked with ague. Similar experimeuts, with like results, have been repeated in Germany. The advocates of the theory that miasma is due to the decomposition of vegetahle remains—notahly Dr. H. W. Harkness—urge in reply to Dr. Salisbury's experiments, that no means wae fouud to separate the spores of the palmella from the gasee and emanations of the earth in which the plante grew. Dr. Harkness also urges, in a paper on the euhject, that the palmellæ grow ahundantly in regions where malaria is not known, where the temperature is so low that malaria cannot exist, that they have been found growing at an elevation of 15,000 feet in the ice-cold water that tricklee from the glaciers of the Himalaya, as well as among the iceherge of Greenland.

The advocates of the germ tbeory urge, that the failure of the chemist to detect miasma by his tests, delicate as they are, ie to he ascribed to the fact that it is organic and composed of few elements, which elements are, in a great part, those of the atmosphere itself, and that they produce no distinctive reactions under the ordiuary processes of analyeis.

If we avoid the discussion of tbese theories and leave the chemist confessing that, as yet, he cannot tell what miaema ie, but aek what facts bave heen noted and recorded in relation to it, we ohtain the reeults of a vast amount of ohservations as to how it originates, as to the conditione necessary for its generation, as to how it is transported and disseminated, and as to its effects on the human syetem, and how these are counteracted. These last I do not dare to discuss, but I will try and condense euch other facte as have been observed, and to the correctness of which there appears to be universal agreement.

Origin and Dissemination of Miasma.

Rich, moist, prolific land, with decaying vegetation, in a climate like that of portions of the interior of California, will produce miasma; and the more favorable the conditions for vigorous and abundant growth and consequent ahundance of vegetation to decay, the larger the amount of miasma generated or given off. Such lands will always be sought hecause profitable for cultivation, notwithstanding the penalty attached to residing upon them. This penalty may he mitigated or perhaps avoided by a knowledge of what has heen observed of the laws governing this cause of disease. If a condensed statement of these observations—for all of which I am indehted to the records of many scientific and medical observers—will be of service iu showing farmers and others living in malarious regions, where they should build their homes and how best to avoid the iufluence of this mysterioue scourge, my purpose iu writing this paper will have heen accomplished.

For the generation of miasma there are required heat, moisture, and decaying or decayed vegetation. The absence of either prevents its development. The heat necessary for its formation must be above 60° Fah., as it does not prevail in regions where the daily average temperature is helow 60°. It therefore does not prevail, as a cause of disease, in high latitudes or on elevated mountains. Heat alone will not produce it, as it is not known in hot sandy deserts. The most favorahle situations for its production are a daily average temperature of over 60° and a moist alluvial soil rich in humus, lying on a clay suhsoil. Iu this temperature it is largely generated where the hottom of a sluggish etream, or the hottom of a pond or reservoir is exposed to the hot sun. It does not appear to he geuerated on land that is clean, dry and well drained. Continuous cultivation of the soil, it is thought, prevents its formation. The drainage of low marshy ground slowly expels it, but the drying up of an inundation usually reproduces it where it had previously existed. At an unascertained temperature helow 60° it is heavier than the ordinary air at the same temperature; at an unascertaiued temperature above 60° it is lighter than the air at the same temperature. In other words, it is condensed by cold, made heavier and falls to the ground, and it is rarefied hy heat and ascends. Free rapid ventilation appeare to dissipate it, while it is concentrated in stagnant air. It is more pernicious at night than duriug the day, because concentrated by the cooler temperature, and for the same reason more pernicious near the ground than at higher elevations. The upper stories of houses are more exempt from it than those near the ground. At night being heavier than the air it clings to the earth and is moved hy the wind, rolling aloug the surface like a low fog. In this way it ascends a slightly sloping surface, but is banked up against a hill, levee or more ahrupt ohstruction. For this reason persons living on the windward side of a levee, a grove of treee or a hill, are more suhject to its influence than those living on the opposite side. Prof. John W. Foster, in his work on the Mississippi Valley, states that the early settlers of Illinois when first subduing the prairie to cultivation found it necessary to build their cabins on the windward side of the land to be cultivated.

Empedocles, 400 years before our era, found it possible to destroy or impede the action of malaria, in one instance hy draining a swamp, and in another by building a high wall to protect an exposed town. It has been observed where our mining reservoire have heen emptied in summer and the deposit remaining has been exposed to a hot sun, that the people living on the eastern side of these reeervoirs were more affected hy it than those living on the opposite eide, our prevailing winde in summer being from the weet. While the reeervoirs are kept full of water, or while lands are kept flooded, miasma does not appear to he produced. It either does not form or the water absorbs it. It is thought not to be generated or at leaet not to rise through a foot or more of water. Dr. W. W. Hall, of New York, who devoted much time to the observing and recording of facts connected with vegetahle miasma, thinks that it is ahsorbed hy water and that the wind will not convey it across a wide and rapid stream. Thie is doubted by other authorities. It has, however, beeu repeatedly noted that while it prevailed on a shore producing much sickness, people in vessels anchored a mile from the shore were not attacked. It is probahly ahsorbed by stagnant water where it is generated, hut does not thereby lose its malignant qualities. Of the numeroue observatione which appear to confirm this view, I eelect one recorded hy Boudin in the *Lancet*. Three vessels sailed from Algiers for Marseilles transporting 800 soldiere, who on shore had all heen exposed to the same atmoepheric conditions. Two of the vessels had heen supplied with good water, the third with water from a marsh. The two former arrived at Marseilles without a sick man, the third ehip lost 13 men and had 120 sick, 98 of whom were afflicted with malaria.

If possible, a house should not he built on made land, over a filling, ou hottom land, on land once the hed of a stream, elough or pond where leaves, grass, wood or other vegetable matter have heen deposited and decayed. If not possible to avoid such situations, then the bouse should he on a mound with free ventilation beneath, and all sleeping roome sbould be in the upper story. Of couree water from shallow wells or stagnant sloughs in such situations sbould not be used for domestic purposes. In the neighborhood of shallow ponds and sluggish or stagnant water, it has been noted that malarious diseases would prevail in an ordinary season, while the inhabitants would escape in both a very wet and a very dry season. This appears to be explained by what has been stated. In the very wet season the ground was covered hy water, and the miasma was uot generated, or did not rise; iu the very dry season the moisture was not there, and it cannot be produced in dry earth While miasma is given off by decaying vegetation it is absorbed or arrested by growing vegetation. No other fact seems to be eo universally conceded as this. Priuitive forests, when left to the undisturbed operations of nature, preserve the halauce between growth and decay, and do uot largely generate it. It does not prevail in the bogs of Ireland, nor in the Dismal swamp of Virginia and North Carolina, while their surfaces are covered hy perpetually growing mosses and other vegetation.

The Influence of Forests.

In a paper on the forest trees of Australia, hy Mr. Bosisto, read before the Royal Society of Victoria, and puhlished in the official catalogue of the Commissioners to tbe Centennial exposition for Australia, he says four-fifths of the vegetation of Australia consists of forests of eucalyptus; and as to the sanitary influence of the forests of this family of trees, he adds: "Australia, on the whole, may be said to he pretty free from virulent endemic or miasmatic fevers, and the latter may be said to exist, only as the eucalyptus recedes."

When forests are cut down and the balance destroyed hetween growth and decay, the means provided hy nature for the absorption of miasma are removed, aud it is left free to poison the air. As has been well stated by Dr. Mitchell, in his essays on malarious fevers, "the insalubrity of a place has the most constant relation to the habits of the living vegetation." This law cannot be hetter illustrated than in the history of the Campagna near Rome. At the commencement of the Christian era it was covered with forests of trees, gardens and villas. On it were erected the magnificent villas of the Emperors Domitian and Hadrian. Pliny, in writing of it during the reign of Vespaciau, A. D. 75, says: "Such is the happy and beautiful amenity of tbe Campagna that it seems to be the work of rejoicing nature. For truly so it appears in the vital and perennial salubrity of its atmosphere, in its fertile plains, sunny hills, healthy woods, tbick groves, rich varieties of trees, breezy mountains, fertility in fruits, vines and olives, its noble flocks of sheep, abundant herds of cattle, numerous lakes and wealth of rivers and streams pouring in upon it." The effect of the destruction of the trees in ehanging this paradisc to a pestilential desert is observed by every traveler. It is now so terribly stricken by malaria that beyond the Church of St. Paul, ahout two miles from tho walls of Rome, I could not see a human habitation to hreak the utter solitude. The people who cultivate small portious of it, go down from the hills cach day, long after the sun has risen, do their work in the heat of the day, and escape hack to the hills again before the sun has set. In describiug the Church of St. Paul, near the Three Fountains in the Campagna, Mrs. Jameson says: "In all the melancholy vicinity of Rome there is not a more melancholy spot than this. A splendid monastery, rich with all the offerings of Christendom, once existed here. The ravages of that myeterious scourge of the Campagna, the malaria, have rendered it a desert. Three ancient churches and eome ruins still exist, and a few pale monks wander about the dismal confines of the hollow in which they etand. In winter you approach them through a quagmire; in summer you dare not hreath in their pestilential vicinity."

The French Investigations.

M. Becquerel, memher of the French Inetitute, in a paper ou "Forests and their Climatic Influence," puhlished in 1867, in giving the effects of the destruction of forests in different parts of France, says: "La Brenne, situated between the Indre and the Creuse, presents a circular surface of more than 125 milee in circumference, or nearly 197,680 acrcs. The eoil is sandy loam resting on a substratum of impenetrable clay, which resists the infiltration of water. It is thickly covered with pools, to which are attributed the intermittent fevers prevalent throughout the district. Ten or twelve centuries ago it was occupied by foreets interspersed hy meadowe and watered by running streams and eprings. Then there existed neither pools nor swamps, and it wae renowned for the fertility of its pastures and the amenity of ite climate. A like state of things appear in Sologne, which represente a surface of 1,112,000 acres, and which hae become proverhial for its insalubrity. The deplorable condition in which we eee it did not always exist. Historical documente show that a great part of this country was of old dotted with woods. Their extirpation has been succeeded by the accumulation of etagnant water, fevers and the atteudant maladies."

In a report to the French government on the waters and foreets of France, made in 1875, the tbe author records the fact that at Palo, a railroad etation between Civita Vecchia and Rome, a piece of woods had stood between this place and a malarious district to the south, and while this remained the place was healthy. This was cut down and presently the south winde brought in the fevers from the pestilential district. Manziana, a place that had been almost wholly free from malaria, suffered in like manner after some shepherds eet fire to an olive forest adjacent. A similar phenomena was observed at Sezze. He adds: "At Supino, the arondissement of Frosinone, formerly passed for healthy, but since the cuttiug off of a piece of woods, the malaria soon became seated, and in a little time many of the inhahitants fell victims to the disease.

Other Official Reports.

A forest of pines existed in the Campagna as late as 1580. It having become tbe stronghold of brigands, it was ordered destroyed by Pope Gregory, XIII. Lancisi records that after its destruction the insalubrity of Rome was notably increased. The island of Mauritius was once covered with dense forests, and was noted for its salubrity. Since 1851 these have been destroyed for their wood, and that the land might be made profitable in the cultivation of sugar cane. The effect of this destruction of trees is given in a letter of Mr. Charles Meldrum, the director of the observatory of Mauritius, to Mr. F. B. Hough, dated August 16th, 1877, and published in his report on forestry for tbat year Mr. Meldrum says: "Formerly, when the interior was densely wooded, a large portion of the rain water was retained, and filtration went on gradually, so that, even in the driest years, the lagoons received regular supplies of pure water, hut uow the greater part of the rain water is carried away to the sea, and hence in dry weather the sun'e rays beat down on slimy, fetid marshes. During torrential rains also the low lands are flooded, and mucb stagnant water and vegetable debris are left behind. The consequence is, that an island, at one time noted for its salubrity, has become a hot-bed of malaria. During the last 10 years the mortality from fever has heen very great. It is during the process of evaporation after heavy rains that the fever becomes epidemic, and only then with a high temperature."

In the Freuch report ou "Waters and Forests," for 1877, in referring to the climate of the city of Guatemala it is stated, that eince the forests whicb existed between that place and San Jose—its port on tbe Pacific—have disappeared, the inhabitants have been exposed to miasma generated on the coast, and new diseases have appeared.

Dr. Bryden, President of the Statistical Office, of Calcutta, in his report of 1869, on epidemic cholera in the Bengal Presidency, says: "Tbe road to Sambalpoor runs for 60 to 70 miles through the forest, which, around Petorah and Jenkfuss, is very dense. Now it is a remarkable fact, hut it is a fact nevertheless, that on this route traversed daily by hundreds of travelers, vehicles and baggage trains, the cholera rarely appears in this extent of 60 miles, and when it does appear it ie in a mild form; hut wben we come to the road from Arang, westward to Chicholee Bungalow, wbich runs for about 90 miles through a barren, treeless plain, we find the cholera every year in its most severe form, the dead and dying lying by the wayside, and trains of vehicles half of whose conductore are dead." Dr. Murray, inspector of the hospitals in the Beugal Presidency, is his report for the same year, gives a number of instances of the influence of trees in preventing the spread of cholera. He says: "In India the fact ie generally believed, and not long ago the medical officer of Jatisgar, in central India, offered a striking proof of it. During the widespread epidemic of cholera in Allahabad in 1859, those parts of the garrison wbose harracks had the advantage of having trees near them, enjoyed an indisputable exemption, and precisely in proportion to the thickness and nearness of the shelter. Thus the Europcan cavalry, in the Wellington barracks, which etand between four rowe of mango trcee, but are yet to a certain extent open, euffered much leee than the fourtb European regiment, whoee quarters were on a hill expoeed to the full force of the wind; while the Bengal horee artillery, who were in a thicket of mango trees, had not a single case of sickness; and the exemption cannot be regarded as accidental, as the next year the comparative immuuity was precieely the eame."

M. Regaud de l'Iele was one of the savans who was eent to Rome in 1810 to investigate the practicability of the drainage of the Pontine marshes. He made au extended report entitled "Causes of the Insalubrity of Air," published in 1816. In that portion relating to the effect of forests, he eays: "When a current of had air, laden with pestilential miasma, penetratee a foreet to a certain extent, it is wholly deprived of these propertiee. The effect of this is observed in the Pontine marshes in which a belt of trees preserve all that is hehind it, while tbe uncovered part is exposed to fevers. The trees therefore tame the infected air and deprive it of its miasma."

Within the past few years some plantations of treee bave been made with the object of improving the eanitary condition of particular localities, notahly near Rome and in Algeria. The evidence of tbe beneficial effcct of thie planting is now beginning to accumulate. In 1874 plantations of the eucalyptue were made ahout the church of St. Paul and the abbey of the Three Fountaine near Rome, which, ae bas heretofore been stated, is one of the most inealubrious and fever-breeding portions of the Cam-

pagna. For the past four years the sanitary condition of its few inhabitants has so much improved that the experiment is considered successful, and the Italian government is extending similar plantations about other fever-stricken localities. From Algiers a report has been made of a military post in which the garrison had to be changed every five days, so virulent was the malaria. A plantation about the post of 60,000 trees of the eucalyptus, has nearly absorbed or arrested the miasma, and rendered unnecessary the frequent changes of the garrison. Parts of the island of Cyprus are so afflicted with malaria, that Sir Garnet Wolseley has asked the English government for an appropriation of £3,000, to be expended in plantations of the eucalyptus about the military posts, and especially near the salt lakes of Larnica.

The commission appointed by the Italian government to report on the means to be adopted for the improvement of the extensive swamps known as the Tuscan Maremme, advised the planting of three or four rows of poplars in such directions as to obstruct the currents of air from malarious localities, and thus intercept a great portion of the pernicious exhalations.

American Experience.

It has been a popular belief in many of the Western States, that the planting of sunflowers about a house, would preserve its inhabitants from miasma. The attention of Lisut. Manry having been called to the subject, he caused several rows to be planted between the Washington observatory and the marshy banks of the Potomac. He has recorded his belief in the fact, that while they were growing, they saved the inmates from the intermittent fevers to which they had been formerly liable. George P. Marsh states that "Maury's experiments have been repeated in Italy, and large plantations of sunflowers have been made upon the alluvial deposits of the Oglio above its entrance into the Lake of Iseo near Pisogne, and it is said with favorable results to the health of the neighborhood."

Delano is a station on the Southern Pacific railroad on the treeless plains of Tulare valley, the nearest station to Tulare lake, and under the direct influence of the prevailing winds that blow, during the summer and autumn, from over the extensive marshes made by Buenavista and Kern river sloughs, before their waters are drained into the lake. During the construction of the railroad and for some years afterwards—relatively to the number employed—more men afflicted with malarious diseases were sent to the railroad hospital at Sacramento from this station than from any other point on the road. In the spring of 1876, the Directors ordered 1,000 of the eucalyptus globulus to be planted in a tripple row near the railroad track between the station and the marshes. These have grown rapidly, and now average more than 25 feet in hight. The yearly average of patients sent to the hospital, with malarious diseases, from this station from 1873 to 1877, was about 25. In 1878 it was reduced to eight. Mr. R. Forbes, who has charge of the records of the railroad hospital, in writing me as to the sanitary condition of different stations on the road, says: "The health of the men all along the line appears to be much improved during the last two years, which is probably due somewhat to the culture of blue gum trees." For the purpose of obtaining statistics of the health of the inhabitants of the village, who were not employees of the railroad, the engineer's department wrote to Mr. Defos du Bau, an extensive wool grower at Delano, who employs many men. In his replies he says: "The population of Delano is nearly 50 persons, but it increases to more than double in March and April, August and September. At these two periods we employ 50 men in our corrals. Intermittent fevers commence in autumn and continue a part of the winter. In 1874 and 1875, with two exceptions, everyone had fever. In 1876 it was the same thing. Out of 45 men employed at the corral, fifteen shearers were taken sick, 48 hours after we had a sand storm caused by a southern wind, and the others were attacked the following day. In 1877 there were but three or four cases amongst our people, and seven or eight among the floating population. In the year 1878 there has been no sickness from intermittent fever. We attribute this change to the trees you have planted, and to those which we ourselves have also planted."

Conclusions from Facts Cited.

From this collection of facts it appears to be clear that while miasma is given off by decaying vegetation, it is also absorbed or arrested by growing vegetation. In temperate climates intermittent fevers do not usually prevail until autumn, about the period when deciduous trees are shedding their leaves and lower forms of vegetation have ripened their seeds and cease to make growth. The eucalyptus globulus has earned the name in the south of Europe and northern Africa of "the fever tree," from its supposed virtues in preventing malarious diseases. Its beneficial effects in this respect I think are to be ascribed not to its odors or resinous gum, but to the fact that it is a broad-leafed evergreen, that it has nearly an equal number of stomata on each side of the leaf, that it is absorbing moisture by the roots, transpiring by its leaves and its chlorophyl is changing sap into woody fiber, when deciduous trees are inert. In other words, it continues to grow after deciduous trees and annual plants have ceased. Prof. Lockwood says it is asserted that a eucalyptus will eliminate from a swampy soil and transpire eight times its own weight of water in 24 hours. All trees arrest or absorb miasma while growing, but the eucalyptus never stops growing in our climate, and therefore its work in this respect never ceases. It is not remarkable for beauty of form, but it is wonderful in its rapidity of growth, has much commercial value for its wood, and for arresting or absorbing miasma, fills a place that cannot be so beneficially occupied by any other tree within my knowledge.

From what has been stated it will be seen how great is the benefit to be derived from the planting of forest trees, and how great is the crime in the wanton and needless destruction of the trees on the borders of our rivers, sloughs and over-flowed lands, and the certain penalty that follows this crime. Without looking to the ultimate effect of the destructive waste of trees on our mountains, hills and plains in altering climate and in creating floods and drouths, but only to the sanitary effect of this waste, I sympathize with wise and good Bernard Palissy, who in 1563 thus complained: "When I consider the value of the least clump of trees, or even of thorns, I much marvel at the great ignorance of men who, as it seemeth, do nowadays study to break down, fell and waste the fair forests which nature did guard so choicely. I would think no evil of them for cutting down the woods did they but replant again some part of them; but they care naught for the time to come, neither reck they of the great damages they do to their children which shall come after them."

Useful Information.

Grape Seed Oil.

Has this ever been made in this State? It seems that Italy and France are getting nervous about the 17,000,000 pounds of grape seed which they are annually throwing away, and in a country which pursues the economies as closely as France, it is no wonder this great leak excites attention. We read that a process has recently been adopted in Europe by which oil is profitably extracted from the grape seeds thrown out at the wineries. The first step in the process is the careful drying of the seeds. Those of the black grape appear to be the best for the purpose in view, the white grape seeds containing a far less proportion of oil. They are then carefully washed free from dirt and mold, again dried, and ground in a mill in the ordinary manner. It is necessary that the meal should be extremely fine, for experience has shown that on this point the quantity of oil obtained from it is chiefly dependent. The meal is then put in large coppers, and a hole scooped in the middle of it with the hand and filled up with water; after which a slow fire is lighted under the caldrons, and their contents stirred about from time to time so as to ensure the perfect mixture of the meal with the water. The fire is withdrawn when the heat has risen to such a point that the hand can no longer be borne in the coppers, and the paste taken to the press in sacks. It will be seen that the process is of the most simple nature, and can be applied with very little outlay in localities where the plant of presses and other apparatus is already at hand for treatment of the olive crop; but even when this is not the case, the extraction of the oil would probably prove fairly remunerative. It is calculated that every hundred pounds of the seeds will yield five or five and one-half pounds of oil. The latter is of a light yellow color, and mild flavor, and without smell. Its specific gravity at 15° C. is 0.9202, and it solidifies at 16° C. The value of the oil on the market is about twice the cost of its extraction, as it is done by the French. It will probably be used as another of the many adulterants of French olive oil, which is sold to us at such high price. Whether grape-seed oil would pay in this State, is doubtful, but it might be tried as a matter of interest.

A new application of the Bessemer process, the invention of Mr. John Holloway, is described in our English exchanges, by which the converter is used to treat iron and copper pyrites, and produce sulphurous and sulphuric acids, and a regulus containing copper. The pyrites are melted in a cupola, and then blown with a blast of air in a Bessemer converter. The sulpur is oxidized into sulphurous acid, which can be dissolved, condensed or further oxidized into sulphuric acid. A rich regulus is obtained, which can be profitably treated for copper, the slag being highly ferruginous, as in the present system of copper smelting. As in the Bessemer steel process, the carbon and silicon in the molten pig iron are the fuels which furnish the heat required in the process; in the new process the sulphur in the pyrites (a more combustible material than carbon) is the fuel. It is said that the new process would avoid the destruction of vegetation which is complained of in localities where pyrites are treated for sulphuric acid.

Making Plaster Set Quickly or Slowly.—In order to make plaster set quickly, mix it with warm water into which a little sulphate of potash has been dissolved. To make it set slowly, mix it with fine slacked lime. The time of setting may be regulated by changing the relative quantities.

Elevation and Temperature.

Dr. C. D. Hunter, of Santa Rosa, has given much attention to the study of atmospheric and climatic phenomena in different parts of the world. He writes for a recent issue of the Santa Rosa *Democrat* an article to show the philosophy of escapes from frosts at moderate elevations, while valleys below are badly bitten. Although all of us know practically that such is the fact, not all are conversant with the reasons therefor, and as the subject is of interest to many who are intending fruit-growing and the like, we shall present in condensed form the atmospheric performances outlined by Dr. Hunter.

It seems that the first clear demonstration that the valleys were more subject to frost than the hillsides, resulted from the establishment of meteorological stations in Switzerland. There the great hight of the mountains and the narrowness of the valleys show their difference much more markedly, and to as great a hight as 5,000 feet. Santa Rosa valley is so large and wide in comparison to the hight of its surrounding hills, that the difference is neither so marked, nor can it extend to so great a hight. Probably in our smaller valleys, and the great Sacramento valley near the foot of the higher Sierras, will be found many low-lying grounds subject to night frosts even late in the spring season.

The main cause of this peculiarity in the distribution of low temperatures is to be found in the but slight heating effect of the sun's rays on the atmosphere. The sun must first heat the soil, and then the soil heats the air. Conversely the cooling of the air is also effected by the soil; and hence the air nearest the soil is always the hottest when the sun is shining, and the coldest when the sun is absent. For the same reason the surface air experiences the greatest changes of temperature. So it comes that the air of the valleys being hedged in by a surface of soil on every side gets rapidly heated when the sun shines, whereas that of the hills has not only less surface for an equal quantity of air, but it is almost constantly in motion, and each new supply keeps down the temperature of the surface soil and air. The glaciers of the Sierras and the snow-capped peaks of high mountains even in the tropics, bear witness to the fact that the direct rays of the sun have but little power to heat the atmosphere; for otherwise the higher we ascended the warmer it should be.

Few have any idea of the extreme changes of heat experienced by the surface soil. When the maximum thermometer in the air will register 70° or 80°, one on the soil may reach 110° to 130°. But even before the sun sets and as its rays cease to heat the soil, the surface rapidly cools down, and after a calm, clear night it will be found, as a rule, from 4° to 8° colder at sunrise than the air four feet above it. Now, as every one knows, cold air is heavier than hot air, hence what forms in the valley remains there. But what of that on the hill? As the air on the hill cools, it begins, like water, to seek its lowest level, and as the cooling process goes on, every watercourse, ditch and hollow becomes a channel down which the cold air flows just as if it was so much water. Consequently near the foot of the hill every little valley and depression of the surface becomes a little lake of the frosty fluid. Here it accumulates in proportion to the stillness of the night and severity of the frost. At the same time the hill surface as it loses its cold air must get a new supply, and this, of course, can only come from above, where the air of the day, being out of the reach of any solid body to cool it, has lost only a portion of its heat. So by night the soil of the hills is constantly bathed with air of a comparatively mild temperature, whilst the valleys receive of cold far more than their share.

Good Health.

Health.

Editors Press:—I have been a semi-invalid for 50 years. I have been obliged to study the conditions necessary to the preservation of health in order to keep soul and body together so long. I will give, measurably, the results of my studies in this line, hoping thereby to benefit others. I love the true reformers of the age. They are, for the most part, philantbropically laboring for the good of mankind; they see evils, and corruptions, and oppressions everywhere they turn their eyes, and labor manfully to lessen them. But the trouble with far too many of them is that they labor *too* assiduously; they go *too* far with their ideas of reform; they ride their respective hobbies to death, and often do more harm than good in the world. Now, my hobby, if I have a hobby, can, I think, be expressed in two words—

Avoid Extremes.

The reformer in theology, seeing priestcraft and error in all creeds and sects, too often strikes at the root of all religion, and would leave us nothing but poor, fallen human nature to depend upon. The reformer in social life, seeing oppression, and tyranny, and corruption in all laws and their administration, is too apt to denounce all order, and law and government, and advocate a system which would inevitably result in anarchy and indiscriminate bloodshed. The reformer in medicine, seeing that drugs kill as well as cure, will sometimes strike loose from all medicine and depend entirely upon unaided nature to affect a cure. These all go to extremes. The happy healing medium is not sought. The old-time doctor denies a drop of water to his fever-burned patient; the hydropathist sometimes drenches him with ice-cold draughts, and soaks him in cold water until all color, and vigor, and life are drenched out of him. The happy medium would be to give him moderately of cold water when he was dry, and bathe him for a few moments in cold, or cool water, when his skin was hot. It is a good rule in these, and many other cases, to do and act in a manner that will make the patient most comfortable, with an honest, intelligent physician to modify somewhat upon occasions, this rule. Pepper and lobelia are good medicines, but I have seen, in the infancy of Thompsonianism, a man pour a heaping teaspoonful of fiery cayenne pepper into his bowl of bread and milk and eat it, when there was nothing the matter with him; and I have heard of taking a lobelia emetic to cure a sore toe. The allopathist will sometimes feed quinine like flour; and the homœpathist, taking warning, perhaps, from the evil effects, will sometimes reduce his dose so a mosquito need not fear to swallow it. There is, doubtless, good in all these various systems, but, carried to extremes, evil results.

Old Truths Good Enough.

Now, I do not expect to add anything new; old truths are good enough, and there are enough of them; the trouble is they are too often neglected or forgotten. The less drugs the better. Take them only when absolutely necessary, and only as prescribed by an upright physician, and then only in the smallest possible doses. They are so uncertain in their effects. Indeed, some noted physicians go so far as to say that drugs have done more harm than good in the world. They are too apt, even when they cure disease, to leave the system in that enfeebled state that some other and more malignant disease will seize upon the patient, when a series of circumstances renders him peculiarly liable. Better, perhaps, to be sick a few days longer, and let nature finally heal, and heal truly, than to cure with drugs, the deleterious effects of which remain for years, or for life, to torment.

Eat Wholesome Food.

Eat the most wholesome and the best cooked food to be obtained. This does not mean what is usually called the richest. The plainer the dish the better, so that it is *good*. It must also *taste* good. If the appetite is perverted with highly seasoned dishes, it should be corrected as speedily as possible by persisteutly eating plainer dishes. It can soon and easily be done. Have a large variety, eat everything that is good, but not at one meal. Here let the smallest number of dishes that will properly satisfy the appetite, suffice. Use very few condiments, and spices, and seasonings. Eat slowly, masticate thoroughly; enjoy your meal to the utmost, but never eat to repletion. Have pleasant subjects for conversation; keep all excitements and passions from the table. Indeed, passions at all times kill, especially the invalid. Keep cool and happy. Bathe once a week—oftener in hot and dusty weather—in warm or cool water, whichever is most agreeable to the sensations. Bathing, followed by a permaneut chill, is death-producing.

Follow Nature,

But here reason must step in, for nature is sometimes perverted. Be very regular in all your habits, regular in lying down and in rising up, regular in eating, and drinking, and sleeping, and be especially careful not to get into the habit of eating between meals. "Let your moderation be known" in all things. Be moderate in eating, in sleeping, in drinking, in labor and in rest. If you have labored hard and are hot and thirsty, drink moderately; if you are very hungry, eat very slowly and very moderately. If meat agrees with you, eat a little; if you are old or feeble, drink a little tea or coffee; if you need stimulants, drink a little wine; but of most of these, I would say, the less the better, and of whisky and tobacco, I would say none. I end with the refrain which I would impress most earnestly upon all, *avoid extremes;* do nothing to excess; and if you have, in a moment of thoughtlessness, overdone, physically, or morally, or mentally, lie idle for a few days and recuperate, and do not, unless you are seriously sick, throw yourself into the hands of a physician, who cannot know your nature as well as you ought to know it yourself.

S. P. Snow.

Tape-Worm in Cucumbers.—The dietetic reputation of cucumbers is bad enough already, but it is likely to become worse, now that Dr. Leidy, of Philadelphia, has discovered that they are liable to be infested with tape-worm. At a meeting of the Academy of Science, Philadelphia, he exhibited a specimen of tape-worm taken from the inside of a large cucumber. It is said to have had all the characteristics of a true tape-worm, but belonged to an unknown species, the peculiarity being that the ovaries, containing the round yellow eggs, are confined to the anterior extremity of the segment.

The Week.

As a whole the mining communities of California have been well prospered so far this season. Water is plenty, and the gold mines continue to yield without abatement. The gold product both from quartz and placer diggings bids fair to be large beyond precedent, and the whole mining population are working with the evident intention of making the most of the opportunity while it lasts. A heavy mining suit has been commenced against the Trustees of the Alta Mining Co., on account of a missing item of $250,000 in their accounts. The agreement between the mining companies and the Sutro Tunnel, is now positively stated to have been signed. The contract is substantially the acceptance of the old agreement of 1866, subject to modifications, principal among which is a reduction of the royalty of $2 per ton to $1 per ton on ores that yield $40 and less per ton; while on ores that yield more than $40 per ton the royalty is to be the same as before—$2 per ton. The officers of the mines are required to furnish the Sutro Tunnel Co. a certified statement of the yield of each mine, and to pay the royalty on the same on the 10th of each month for the product of said mine during the calendar month. The mining companies are to advance the tunnel company $70 per linear foot, without interest, for the construction of branch lateral drifts north and south connecting with said tunnel. The tunnel company is to repay this advance at a future time. The mining companies will be permitted to assist in the construction of the lateral branches, and for all work thus done the tunnel company is to repay the mining companies at the rate of $70 per linear foot. It is also provided that the tunnel company shall have the tunnel in readiness for the free passage of water of whatsoever temperature drained from the mines, and that the latter shall be at liberty to pump the same at the expiration of 90 days from the signing of the articles, or at any time within that period when the tunnel company shall give consent. The payments to the tunnel company for the work it performe in running the branch lateral drifts are to be made on the 5th of each month at the above rate ($70 per linear foot) for the number of feet run within the preceding calendar month. The Sutro Tunnel Company has for several days been preparing to resume work in the tunnel. A thousand men will be taken on to dig the sub-drain.

What is Being Done in the Mines.

The business of mining throughout most parts of California is just now in a very active and prosperous condition. This industry seems to be, in fact, making satisfactory progress in nearly all parts of our Pacific States and Territories. From every quarter the accounts that come to hand are of a cheerful tenor, the productive mines yielding their full complement of bullion and many new finds of importance being reported. While so much activity and such generally good results are everywhere noticeable, the business of gold mining is at the present time especially lively in California, where at this season of the year it can be pursued to best advantage. This is harvest time with our hydraulic miners, who reap while our farmers are plauting. On this class of claims gravel washing is now being pushed diligently day and night and will so be continued without intermission, except through accidental interruption or for the purpose of cleaning up, till the end of the water season, which promises to be much more extended than the miners had for a long time dared hope for, and may even be as protracted as in ordinary years, despite the dry winter.

There is reported to be a pretty fair stock of snow on the mountains, a good deal having fallen during the recent storms. As these later additions are underlaid by a considerable body of more compact snow, the whole will be likely to keep the streams tolerably well replenished till mid-summer or later. For several weeks past this class of miners have almost everywhere had plenty of water, and, as the weather has meantime been warm, they have been able to run to good advantage. A great deal of gold has already been taken out, and should the season continue favorable a large production may be counted on from this source the present year. It is not expected that the amount of gold gathered by this process will hereafter undergo any rapid expansion. The quantity of water available for washing having been about all appropriated and applied to that purpose, there is left little chance for enlarging the bullion product, which can now only be increased through enlarged water catchment and storage, which has also about reached its greatest practicable limit. The owners of these properties have, however, through the construction of additional reservoirs and ditches and the introduction of more perfect apparatus and powerful explosives, brought the whole to a condition of such efficiency that they will be able to maintain the present rates of production for a long time to come, and may, through some increment of water supply, be able to add somewhat to the yearly aggregate product now turned out.

Besides the hydraulic washings, the late copious rains have imparted new life to certain other branches of placer mining, a good deal of which is now being done in the shallow diggings and dry ravines, where operations can be carried on at such times only as the present, when water is furnished to them by the rains and without cost. In some of these localities there still remains a good deal of auriferous ground, and as the present tolerably full and long continued water supply has been taken advantage of to work them extensively, these usually non-productive placers will contribute materially towards swelling the bullion stock of the current year. One good feature of these dry diggings consists in the fact that they remain for the most part unclaimed, and requiring but little outlay for tools and equipment and nothing for water, can be profitably worked by men of small means; many of whom in favorable seasons like the present repair to these spots and for several months earn satisfactory wages. As they can be worked but for short periods at a time and often only at long intervals, these fruitful patches will hold out for a long while—a refuge for the industrious dead-broke—a sort of placer preserve for the poor man.

The drift claims already opened are yielding liberally, and much new ground is in process of exploration and development. About Damascus and elsewhere along the Forest Hill divide new tunnels are being driven and new shafts put down to reach the old pliocene channel that passes through that region of country, and which wherever worked has been found prolific in gold. As some of these works have now about reached their objective points, it may be expected that they will soon begin to reimburse expenditures made on their account, and finally earn large profits for the owners. In different parts of Sierra county mines of this class are being operated with excellent results, much prospecting being also done.

In California our mines, by reason of the varied character of this industry, may be said to be always in bonanza. What, between hydraulic, vein, drift and our other forms of mining we are at all times able to accomplish, bullion production goes on steadily and without ever experiencing any entire cessation. We are always gathering gold at some point and by some process or another. And it will here always be so, our quartz reefs, and gravel banks and dead rivers affording inexhaustible deposits of gold-bearing material, to say nothing of new sources likely yet to be opened up and our silver mines destined soon to come in as an additional bullion-making factors. The stranger or casual observer visiting now our mountain towns would get the impression that they were without business and almost without population. Few men would be seen upon the streets or about the saloons and other public places. There would be an apparent dullness and absence of hustle denoting anything but an active and prosperous condition of things. But the eye of the experienced observer would see in all this the evidence of thrift and good times for all, knowing well that the miners, upon whose success all are dependent, were busy in their claims, improving the opportunities now afforded for washing the gold-bearing gravel to the utmost. In these mining districts a town swarming with people is significant of empty pockets, long credits and hard times, while a general cleaning out of the place points to an opposite condition of affairs.

Reading the Stars to a Bad Purpose.

The world has never been without its Cassandrias, and just now it is having a surfeit of these ill-foreboding prophets. Sometimes these people of evil omen come forth to cast the world's horoscope in the name of science, and sometimes in the character of biblical interpreters. As many as three or four times within the recollection of those now living the Millerites or Second Adventists have fixed the time for the world's final destruction, their predictions being based upon the peculiar expositions given of various passages in Scripture. Twenty years ago the past winter the appearance of a comet inspired a widespread terror, certain pretenders to astronomical knowledge having given out that the annihilation of the earth by this celestial tramp was a thing quite within the limits of possibility. And now the approaching conjunction of certain planets affords this same class of pretenders an opportunity to ventilate their learning and inspire the ignorant, the superstitious and the emotional with a dread of impending evils at the same time. Opportunities of this kind occurring only at such long intervals are not to be neglected by these sensation mongers. Hence we find they are being turned by this class to good account.

We are told that the direst calamities await only the coincidence of these heavenly bodies to be precipitated upon our doomed world and race. Next year the four great planets—Jupiter, Uranus, Neptune and Saturn—will be in perihelion—will have reached their nearest approach to the sun, and then evils countless and unspeakable are to be let loose upon the world. The influence of these planets when brought into that position will be, we are assured, exceedingly pernicious to the earth and the people upon it. Indeed, some of these great members of the solar system exert, it would seem, at all times a baneful influence upon our little planet—entertain, as it were, a grudge against it. All these heavenly bodies except Jupiter are unfriendly to us—are, to use the language of astrology, *malefic:* Jupiter alone is *benefic*—kindly and well disposed towards us. But this will not avail to save us from these threatened evils; for, although he is much the largest member of this planetary quartet, his beneficent influence will be nullified by the much greater power for evil possessed by his associates; and which, when the whole set are brought in perihelion, they will be able to exert with deadly effect.

Having so obtained the mastery, the influence of these unpropitious planets will begin to manifest itself in the contamination of our atmosphere, causing widespread famine, pestilence and death. The plague and other incurable diseases will prevail, the waters will become putrid, all nature will be sick. Animals will die, even the fishes will perish and mankind be almost wholly swept from the face of the earth; only on the Pacific coast, where these malign influences are to be exerted with less power, will any considerable number of the human race be spared. As no reason has been assigned by these wise men for this letting up on the inhabitants of the Pacific coast, we are left to infer that this will be due to their greater moral excellence. We find in the case of Lot, of Bible fame, a precedent to justify such conclusion. But even here, we are not to make good our escape altogether. Persons of vile, intemperate and gluttonous habits—who are unclean, eat to excess, drink whisky and suck tobacco, will have a close call, and very likely go the way of the rest of mankind. As a large proportion of our population are addicted to these hurtful and unseemly practices, they, too, may be considered exposed if not doomed to early destruction.

As warrant for these dire predictions our star-gazers, referring to history, find that the world was afflicted in the manner here portended on every occurrence of these planetary conjunctions in the past. Never have these orbs been in perihelion, or even so many as two or three of them, without bringing upon our race these overshadowing disasters. It was so in the year 542, and again 1665, when two of these malignant planets, Mars and Saturn, were coincident; and why should not like conditions now be attended with like effect; or rather, why should not these effects, when there are three of these planets conjoined, be even greater now than then. Shall we not be instructed by history and, admonished by the sad experience of past ages, hasten to adopt such measures as may seem best calculated to protect ourselves against these impending calamities. Nay, they are not merely impending: some of them have arrived; they are beginning to precipitate themselves upon us. In the plague now prevailing in Russia, we have a presage of their early coming, if not tangible evidence of their actual presence. That disease is the *avant courier* of the multitudinous ills with which we shall be visited. It was a godsend, this plague, to these vaticinators of evil. Coming so timely it imparted to their forebodings an air of probability, and has since helped to keep them in countenance with the ignorant and credulous public, if, indeed, its appearance did not suggest to them the idea of assuming the prophetic role as they have done. In the partial diminution of this dread disease these astrological savants must see cause for alarm, as tending to impair confidence in their predictions and so diminish their stock in trade.

The followers of these "star-gazers" are apt to be numerous, including that large class of quid-nuncs, simple and emotional, who love the horrific, believe in signs and consult fortune tellers, who for a small fee are ready to inform them that "it 'pears like" something dreadful, good or bad, is about to happen. These emotionals are fond of the dire and woful, provided always the woes decreed have been allotted not to themselves but to others. Now this proclivity to consult the future and sup on the supernatural and horrible is a constitutional infirmity with many people, and they are not to be blamed for its existence or for seeking ways and means for its gratification. Yet, as it is not a healthful or rational propensity, and its indulgence has a mischievous tendency, it is the duty of the press not to encourage it, nor minister to its indulgence; but, on the contrary, to labor for its suppression, informing these misguided people how little cause there is for alarm.

In the first place it should be remembered how these prognostications about the world coming to an end at a fixed time, and all similar predictions as uttered in our own day, have proved entire failures. Then mankind are prone to believe that the ills, incident to the present time, are peculiar and greatly in excess of those suffered by preceding generations. Hence, the wars and famines, the fires and floods of to-day, are regarded as something, exceptional and pointing to some signal catastrophe in which they are all to culminate. With the astrologer, these multitudinous misfortunes are to reach consummation with the conjunction of the planets. With the religion enthusiast, this will take place on the second coming of the Messiah, with the Aztec when Motezuma returning shall deliver his people from the thrall of the conqueror, and with the Latter Day Saints when Joseph Smith, or some other prophet, reappears on earth in bodily form once more. Now these things are believed in by millions of people, some of whom have been awaiting for these events to transpire for generations and even centuries; and notwithstanding the non-fulfillment of these predictions, their faith in them remains fervid and steadfast.

Difficult as it is to disabuse their minds of these impressions, it is still the duty of all who occupy anything like the position of public teachers to inform this class of persons that there is little or nothing to justify their apprehensions. The truth in regard to these planetary bodies is, that, while they probably always exercise some influence upon the earth and its inhabitants, this influence is exerted through the sun, and is no greater at one time than another. While they are, when in perhelion, nearest the sun, they may be, and generally are, the farthest from the earth, which ought, therefore, to be less affected by them at such time than any other. Now, the sun is so many million times larger than these planets all put together that any effect they can have upon that luminary, even when nearest to it, must be small, indeed. The earth, in making its annual circuit round the sun, comes at some points in its path 3,000,000 miles nearer to that orb than at others, and yet we are not sensibly affected by this greater nearness. Though Jupiter is 12 times larger than our earth, it is composed of matter so much more etherial that its powers of attraction are barely 12 times greater than those of our planet, the power exerted by this force being directly as density and inversely as distance. What is true of Jupiter is true also of Saturn, this disparity between the latter and the earth being still greater. These two are much the largest planets in the solar system, and if their influence upon the sun, and through it upon the earth, is likely to be so little, how infinitesimally small must be the influence so exerted by these lesser planets. So little density have these orbs and such distances are they at all times from the earth that their effects upon the latter must be inappreciably small.

Let, therefore, all who have been alarmed dismiss their fears upon this point. There are plenty of good reason apart from this apprehended scourge why people should take measure for the better preservation of their health, and one would almost feel warranted in terrifying them into some amendment of their present beastly habits, were it not that upon the removal of the cause they would probably relapse, and as an excuse for so much self-abstinence plunge at last into greater excesses than ever. It would, therefore, be as well for the masses perhaps to turn a deaf ear to these portentious forebodings, get rid of their fears and live on as before. The dread of disease, if it do not invite, has a tendency to lay the human system open to its attacks. Excessive fright has been known to bring maladies upon those who would no doubt otherwise have escaped. We have all far less to fear from this approaching conjunction of the planets than from our own excesses and manifold evil habits, which are depopulating the world more rapidly than has ever been done by the Black or any other plague.

New Problems in Mensuration.

[Read before the California Academy of Sciences by Prof. George Davidson, March 3d, 1879.]

The following problems form a continnation of the series commuaicated in part to the *Journal of the Franklin Institute*, in 1866, aud to the California Academy of Sciences, in 1872 and 1873. These, and others to be presented, were completed in 1874, but a pressure of duties has prevented their heing brought to the notico of the Academy.

XIII. Given the height h and the base b of a plano triaagle (Fig. XIII.) todctermine, in terms of the given height and base, the consecutive heights and bases of similar hut hollow triaugles with a central triangle (haviug equal aroas with eaoh other) into which ths given triangle is required to be divided.

To divide the given triangle into n hollow triangles aad central triangle, let h the height, and b the base; x, y, z, etc., the consecutive heights; x', y', z', etc., tbe consecutive hases of the required hollow and central triangles; $(w-1)$ and w the last two heights, and $(w'-1)$ and w' the last two hases; then

$$x^2 = \frac{(n-1)h^2}{n} \quad : \quad x'^2 = \frac{(n-1)b^2}{n}$$

$$y^2 = \frac{(n-2)h^2}{n} \quad : \quad y'^2 = \frac{(n-2)b^2}{n}$$

etc., etc., etc., etc.

$$(w-1)^2 = \frac{2h^2}{n} \quad : \quad (w'-1)^2 = \frac{2b^2}{n}$$

$$w^2 = \frac{h^2}{n} \quad : \quad w'^2 = \frac{b^2}{n}$$

XIV. Given the heights h, h', and the bases b, b', of a hollow triangle with parallel sides (Fig. XIV) to determine in terms of these heights aud hases, the consecutive heights and hases of the similar hollow triangles having equal areas, into which it is required to subdivide the given hollow triangle.

To divide it into n hollow triangles let h' equal the height, and b' equal the hase of the outer triangle; h eqnal the height and b the hase of the inner triangle; x, y, z, etc., the consecutive heights; x' y', z', etc., the consecntive bases (hoth reckoned from h', b'); $(w-1)$ and w the last two heights, and $(w'-1)$ and w', the last two hases; then

$$x^2 = \frac{h'}{b'}\left\{\frac{(n-1)\,b'h' + bh}{n}\right\}$$

$$x'^2 = \frac{b'}{h'}\left\{\frac{(n-1)\,b'h' + bh}{n}\right\}$$

$$y^2 = \frac{h'}{b'}\left\{\frac{(n-2)\,b'h' + 2bh}{n}\right\}$$

$$y'^2 = \frac{b'}{h'}\left\{\frac{(n-2)\,b'h' + 2bh}{n}\right\}$$

etc., etc., etc.

$$(w-1)^2 = \frac{h'}{b'}\left\{\frac{2b'h' + (n-2)\,bh}{n}\right\}$$

$$(w'-1)^2 = \frac{b'}{h'}\left\{\frac{2b'h' + (n-2)\,bh}{n}\right\}$$

$$w^2 = \frac{h'}{b'}\left\{\frac{b'h' + (n-1)\,bh}{n}\right\}$$

$$w'^2 = \frac{b'}{h'}\left\{\frac{b'h + (n-1)\,bh}{n}\right\}$$

XV. Having suh-divided the given hollow triangle, as in prohlem XIV., into any number of similar hollow triangles of equal areas with each othcr, it is required to determine, in terms of the two given heights and hases, the consecutive heights and bases of the required similar hollow triangles formed inside the given hollow triangle, each hollow triangle having equal areas with the given suh-divisions. (Fig. XV.)

Suppose the given hollow triangle is suh-divided into p similar triangles of equal areas with each other; and that there are required n interior similar hollow triangles of equal areas with the foregoing; then let h' equal the height and b' equal the hase of the outer given triangle; h equal the height, and b eqnal the hase of the inner given triangle; and let i', i'', i''', etc., represent the consecutive heights, i, i', i'', etc., the consecutive hases of the required triangles reckoned from h and b; and $(w-1)$ and w the last two heights, and $(w,-1)$ and w' the last two hases; then the hase and height of the nth inner one are

$$i'^2_n = \frac{b}{h}\left\{\frac{(n+p)\,bh - nb'h'}{p}\right\}$$

and,

$$i^2_n = \frac{h}{b}\left\{\frac{n+p)\,bh - nb'h'}{p}\right\}$$

XVI. Having sub-divided the given hollow triangle, as in problem XIV. into any number of similar hollow triangles having equal areas witb each other, it is required to determine, in terms of the given heights and hases, the consecutive heights and hases of the required similar hollow triangles formed outside the given hollow triangle, each additional hollow triangle having equal area with the given sub-divisions. (Fig. XVI.)

Suppose tho given hollow triangle is suh-divided into p similar hollow triangles of equal areas with each othor; and that there are required n exterior similar hollow triangles of equal areas therewith, then let h' equal tho height and b' equal the haso of the outer given triaagle, and h equal the height and b equal the hase of the inner given triangle; let o', o'', o''', etc., represent the consecutive heights, and o', o'', o''', etc., the consecutivo hases of the required triangles reckoned from h'; and $(w-1)$ and w the last two heights, and $(w'-1)$ and w', the last two bases; then the hase and height of the nth outer triangle are,

$$o^2_n = \frac{b'}{h'}\left\{\frac{(n+p)\,b'h' - n\,b\,h}{d}\right\}$$

and

$$o^2_n = \frac{h'}{b'}\left\{\frac{(n+p)\,b'h' - n\,b\,h}{p}\right\}$$

Rolling Wheat to Market.—A new idea is advanced in our Chicago exchanges which amounts to literally rolling the grain into the markets. It consists in the invention of a circular car, 6 feet 6 inches in diameter, which does away almost entirely with hearing and friction on the axle, these heing only of sufficient hearing to provide simply for draft. The tire is of the same circumference as the car, which is cylindrical, and rolls directly on the track. One ton weight of car carries three tons weight of freight. Under the old system one ton weight of car carries one ton. It has had the favorable notice of railway experts, and if it proves what is claimed for it, will revolutionize railway carriage in some importaat directions, and in so far, of course, chcapcr freights, giving, it is thought, from 10 to 20 cents per hushel more to the farmer on wheat, according to the distance carried, than he now receives.

Oregon is pressing claims for damages by Indian wars.

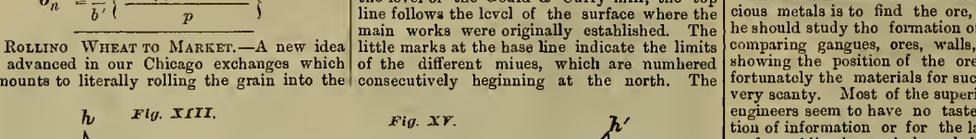

DIAGRAM SHOWING PAY CHUTES IN COMSTOCK LODE.

Pay Chutes in the Comstock Lode.

Editors Press:—On the 13th of May, 1876, you published a communication from me presenting a theory of the division of the Comstock lode into pay chutes and barren chutes, my reasons for it, and an engraving of the lode, showing the large bodies of rich ore, and the situation of the supposed chutes. In the three years that have elapsed since that date, $25,000,000 have been expended in exploring the lode, and all the additional evidence goes to strengthen the theory. The ore bodies found in the Sierra Nevada and Alta come within the limits of pay chutes not shown in my diagram made in 1876, but contribute to confirm the principles on which it was constructed.

The accompanying engraving, based on the map drawn by Mr. Parkinson, several years since, is intended to show a vertical section of the lode, drawn on a scale of 2,000 feet to the inch, as seen in imagination from the east looking westward. The base line is 3,000 feet below the level of the Gould & Curry mill; the top line follows the level of the surface where the main works were originally established. The little marks at the base line indicate the limits of the different mines, which are numbered consecutively beginning at the north. The following is a list of them with the length of each in feet.

No.	Mine.	Feet.	No.	Mine	Feet.
1.	Utah	1,000	12.	Chollar	1,400
2.	Sierra Nevada	3,325	13.	Bullion	943
3.	Union	575	14.	Exchequer	400
4.	Mexican	000	15.	Alpha	306
5.	Ophir	075	16.	Imperial	085
6.	California	000	17.	Yellow Jacket	957
7.	Con. Virginia	710	18.	Kentuck	93
8.	Best & Belcher	536	19.	Crown Point	541
9.	Gould & Curry	617	20.	Belcher	1,008
10.	Savage	771	21.	Alta	600
11.	Hale & Norcross	400			

Between the Belcher and the Alta, a distance of about 3,000 feet, I have not put down the mines, as there is some dispute about the situation of the vein. I confidently believe from the character of the ore found hy the Alta and Justice that both have heeu at work on the main Comstock lode, though common opinion for a long time placed it far west of them.

The dark portions of the engraving are intended to represent harren chutes; ths middle tint showa the pay chutes, which are harren over most of their area, and yet contain all the valuable deposits; the light color indicates the rich ore bodies; and the white lines running down from the surface show the main shaft.

Five pay chutes each nearly a quarter of a mile loug, horizontally, appear in the engraving, and between each adjacent pair, there is a harren chute of equal size. Tbe first pay chute commoneing at the north, contains a hody of rich ore in the Sierra Nevada and Union mines, but has produced neither dividends nor any considerable quantity of mineral as yet. The second pay chute discovered at tho surface in 1860, was very profitable for three years, then yielded uothing for 10 years, and for the last five years has heen profitahle. It has paid $140,000-000, gross, to the Mexican, Ophir, California and Consolida ted Virginia companies. The third, appearing in the Gould & Curry, Savage, Hale & Norcroas and Chollar mines, has turned out $40,000,000. The fourth, known as the Gold Hill bonanza, was worked at first at the surface as a gold placer; then mills were established to save the gold, losing most of the silver; and silver mills have succeeded them. The ground now owned hy the Imperial, Yellow Jacket, Kentuck, Crown Point and Belcher has produced $90,000,000. The fifth pay chute has yielded several millions, mostly to the Justice, hut has paid no dividends.

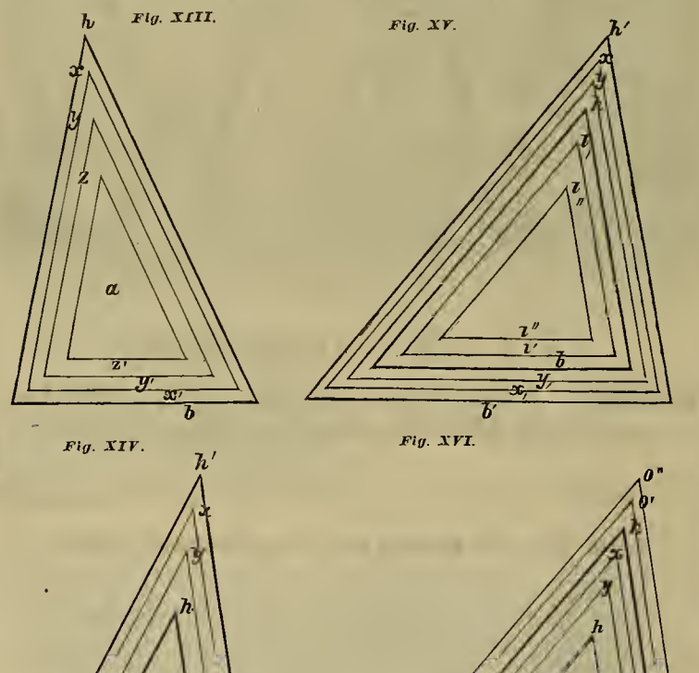
Tho main husiness of the miuer for the precious metals is to find the ore, and to do that he should study tho formation of the veins, hy comparing gangues, ores, walls, and diagrams showing the position of the ore hodies. Unfortunately the materials for such a study are very scanty. Most of the superintendents and engineers seem to have no taste for the collection of information or for the lahor of writing up for publication such knowledge as forced itself upon their attention. No comprehensive essay on the distrihution of ore in the gold and silver lodes of California and Nevada, has been printed; and careful descriptions of the mineralogical formation in even the richest mines are extremely rare, if not entirely lacking. There is a question whether the rules deducible from observations taken in auriferous quartz are applicable to silver lodes, though the presumptions are in favor of an affirmative answer, siuce hoth classes of mines contain the same two precious metals, in varying proportions. There are no gold mines without silver, and few silver mines without gold.

In reference to gold quartz, we know that the lines hetween the pay ore and the harren gangue in rich lodes usually run in nearly parallel directions at a angle of not less than 30 degrees to the horizon, dividing the vein matter into pay chute and harren chute; that the ore in a pay chute of a "milling" vein is a continuous hody; that the ore in "pocket" veins is found in hunches distrihuted in courses which are called "pay chutes" hy "pocket" miners; that if there are several pay chutes in a lode, they usually dip in the same direction and at the same angle to the horizon; that the wider and richer the vein and the more uniform the quality of the ore, the longer horizontally are the pay chutes; and that frequently every pay chute has some peculiar feature enahling old miners familiar with it to distinguish its ores.

Without pretending to have conclusive evidence, and partly for the purpose of providing a hasis for investigation and discussion, I claim that those principles apply to the Comstock; that all the facts observed in working that lode are in harmony with them; that the extensive and costly explorations made hetween the Utah and the Justice inclusive—a distance of more than four miles in the last 19 years, should hy a hundred chances to one have furnished proof against my theory if it did not apply to the Comstock; and that when the proof is conclusive, one practical result will he the saving of at least $3,000,000 annually in the cost of exploration. The engraving from my drawing—for which I do not claim perfect accuracy—is in harmony with the theory.

Now we have a considerahle body of information ahout the distrihution of the ore in auriferous quartz veins, and much more might he collected with systematic effort by half a dozen industrions and intelligent superintendents. In large and rich veins it is observed that the vein matter is divided into harren gangue and pay ore; that the ore extends in a pay chute in a continuous hody, streak, with very uaiform direction, dipping downwards from the surface; that if there are several pay chutes in one vein, all dip at the same angle to the horizon; that the wider and richer the lode, the longer horizontally are the chutes; that each pay chute has usually some peculiar feature so that the miners can distinguish its ores from others; and that the first business of the miner is to understand the size, dip and character of the pay chute. I think I have said enough to show that the distrihution of ore in silver mines deserves more attention than it has yet received from our mining community.

John S. Hittell.



NEW PROBLEMS IN MENSURATION.

Mining & Scientific Press Patent Agency.

PATENTS obtained promptly; Caveats filed expeditiously Patent re-issues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing.

The ablest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Barlow J. Smith, M. D.

Consulting Physician,

Professor of Phrenology and Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenologica Institute, 635 California Street, above Kearny.

This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervo-vital derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-motorpathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermal, Russo-Turkish and Medicated Baths given daily.

Mrs. Dr. Smith as Matron has charge of the female bathing department.

DR. SMITH has practiced Phreuology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiognomy, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness; whether CONSUMPTIVE, DYSPEPTIC, RHEUMATIC, APOPLECTIC, NEURALGIC, LEUCORRHŒAL, or SEMINAL. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds.

Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Fowler and Wells' charts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph.

Phrenological or Physiognomical examinations without charts, $1.50; with charts, from $2 to $3.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 8 P. M. Sundays from 9 A. M. to 12 M.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and placer mining in various parts of the Pacific Coast. Over five hundred orders have been filled, and the demand is constantly increasing. A large number of these Plates were sent to Snake River mines, Idaho, last year, and a great many orders are being filled for them this season. Circulars containing full instructions for working these Plates sent with each order. Old Mining Plates bought or taken in exchange for new Silver Plated Plates, and full value allowed. Gold extracted from old Plates at a moderate cost by a new and economical process. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed.

Mining Men and the public generally are cautioned against unprincipled and irresponsible parties traveling through the country, endeavoring to secure orders for very inferior qualities of Silver Plated Mining Plates.

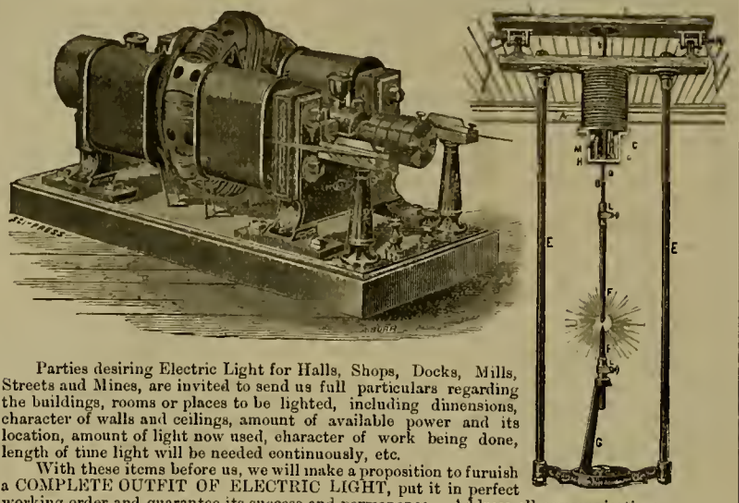
ELECTRIC LIGHT.

BRUSH PATENT.

The Best, Cheapest, Cleanest, and Most Powerful Light in the World.

In daily use at the Palace Hotel and the Union Iron Works, S. F.



Parties desiring Electric Light for Halls, Shops, Docks, Mills, Streets and Mines, are invited to send us full particulars regarding the buildings, rooms or places to be lighted, including dimensions, character of walls and ceilings, amount of available power and its location, amount of light now used, character of work being done, length of time light will be needed continuously, etc.

With these items before us, we will make a proposition to furnish a COMPLETE OUTFIT OF ELECTRIC LIGHT, put it in perfect working order and guarantee its success and permanence. Address all communications,

S. F. TELEGRAPH SUPPLY CO.,

WM. KERR, President,

San Francisco, Cal.

Ingersoll Rock Drills.

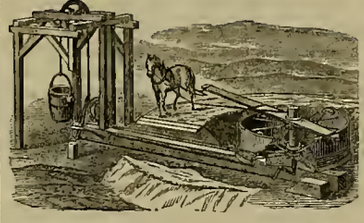
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

[Continued from page 197.]

GOOD HOPE DISTRICT.

PROMISING MINES.—*Silver State*, Mar. 22: Four or five claims are being worked at present, and many others have been located. The principal claims are the Silver Brick, Buckeye, You and I, and Aurora, from each of which fine-looking ore has been taken. One of the owners of the Silver Brick recently returned from a visit to his mine, bringing with him some fine specimens of horn and ruby silver. It was found in a crosscut which was started on the 60 level of the mine, and is said to be an average sample of the ledge. No assay of it has yet been received. Some work has been done on each of the other claims, but not enough to form a correct idea of their value.

PARADISE DISTRICT.

PARADISE VALLEY MINE.—*Silver State*, Mar. 22: The Bray cut has been driven ahead 16½ ft, all in first-class ore. Face of this cut is about four ft wide, which assays about $200 a ton. No. 2 has been advanced nine ft, and is now in 121 ft. Face of this tunnel continues to show considerable sulphurets. No. 3 is getting wider and is looking considerably better. Eight ft has been made, making a total length of 148 ft. Have had the miners from this drift doing other work during the week; hence the short distance run. In the open cut just above No. 3, advance has been 18 ft. Ledge is full of headers crossing at right angles to the veins. These veins vary in richness. Some are nearly all ore, while others are not so good. Course of vein nearly due south, and dips to an angle of about 80° to the west. Continue to ship usual amount of ore to Rye Patch mill. Last two carloads assayed $202 per ton.

THE MOUNT ROSE.—This mine is developing finely. The main shaft has attained a depth of 60 ft, and is being sunk at the rate of two and one-half ft a day. The crosscut is in 45 ft, and what is known as the east drift, 70 ft. This drift is in good milling ore, which is being shipped to Torrey's mill. Very rich ore is now being found in the mine. It contains wire gold, horn silver, and bromide of silver, and assayed $10,000 to the ton in gold and silver. Twenty men are now employed on the mine.

THE BIG PRIZE.—This company is taking out ore right along, employing about 10 men. The mine was recently bonded by a San Francisco company for a short time, but the owners have not stopped work on this account, and do not care particularly about having the sale consummated.

ARIZONA.

OLOKE DISTRICT.—*Silver Belt*, Mar. 14: Rich ore, sulphurets and glance has been struck on the hanging wall of the Buckeye at the depth of 235 ft. The vein is 10 ft in width, containing fair milling ore from wall to wall, with a two-ft streak of very high grade ore. The Pioneer, property of Geo. Scott, is developing well; has a shaft 50 ft in depth sunk on the hanging wall. The ledge has not been cut to the footwall, hence its width can only be guessed at. One hundred and fifty tons of $100 ore is piled upon the dump awaiting the erection of a mill in that vicinity. In the Stonewall 230 level good ore has been struck in the whole face of the drift.

SILVER DISTRICT.—*Sentinel*, Mar. 15: There are now over 90 men in Silver district, and more are coming in. Hughes' shaft is now down over 50 ft, in first-rate ore. The Silver Glance is turning out some very rich rich ore. An accidental strike of rich ore was made lately in the wash north of Iron Cap. Some of the boys started to dig down in the gravel for water. Within a few ft they struck a seam of high grade ore, of which several sacks were filled that same day. The new find is very promising. Good accounts come from all the mines up there. Nuggets or ore claimed to be worth $2 per pound are being washed out of the gravel north of the Red Cloud.

IDAHO.

THE BUCKEYE.—*Silver Reef Miner*, Mar. 15: The mine in its workings is yet in its infancy, the greatest depth reached as determined by the inclines, not being above 150 ft. The main workings are on or near the south end of the claim, adjoining the Last Chance, and in a distance of 300 ft, five inclines have been sunk by chloriders. Those parties, after taking out many thousand dollars' worth of high grade ore, through the transpiring of their leases, retired leaving large bodies of second and third grade ore in sight, and the rich streaks of the veins from which they extracted wealth still going down. At the north end of the claim, where it joins the Kenner and Neutral, it is being prospected by three shafts sunk by chloriders, who at the present time have about 200 tons of high grade ore, worth over $160 to the ton. In the workings of Mr. Archy Florand, Mr. Branham now has a number of men employed sinking a working shaft and putting in an excellent whim for raising ores. The depth of the workings at this point are about 120 ft, and a large quantity of ore of various grades, ranging from $30 to $200 per ton is in sight. It is the design to work this part of the mine in a systematic manner, and there is no doubt that from this shaft alone sufficient ore can be extracted to run the three-stamp mill which does the crushing for the mine. About 20 tons of ore is worked per day. The Buckeye needs greater milling capacity. If the owner would put up a five-stamp mill at the mine, he could clear a few hundred thousand dollars in a short time. Mr. Branham, the owner, has secured a patent to his property. He employs at present 23 miners, and there are about a dozen chloriders still at work on the Buckeye. One hundred men could be profitably employed on the mine. The ore milled from the Buckeye has averaged $58 per ton.

OAMERINUS ITEMS.—*World*, Mar. 18: The tunnel started by Wm. O'Neil, to prospect the Forest Queen mine, was started on the ledge, followed 20 ft, and then discontinued on account of a heavy rush of water. A depth of nine ft was obtained. The ledge matter is eight ft wide, four ft being in quartz and the remainder stratas. The center streak of the ledge proper is from six inches to a foot in width. From this the best prospects are obtained. Mr. O'Neil is convinced that the ledge is an extension of the Magna Charta. The indications for a monstrous mine of richness are good. The surface on both sides of the ledge contains gold, which is a splendid indication. Work is going on in the Forest King, night and day. A depth of 125 or 130 ft has been reached, and the men are stoping. The ledge in the bottom of the shaft is five ft wide, and the ore good.

MONTANA.

NOTES.—*Miner*, Mar. 11: Some excitement in prospector's circles has lately been caused by the developments made on the Silver Shield lode, situated close to the North Star, and about a mile north of the Rainbow. The lode is four ft wide, and carries very high grade free-milling ore, some of it ranging as high as 300 ounces per ton. The title to the ground is in dispute, owing to repeated re-locations. Messrs. Nolan & Savery, owners of the famous Cable mine, have resumed work in the Cameron tunnel with the intention of extending this adit to the lode, from which it is now distant 500 ft. The present length of the tunnel is 650 ft. It will reach the lode 90 ft below the lowest workings. A month ago, in beginning work in this claim, Messrs. N. & S. concluded to run some distance further, a prospecting drift, following the lode, 30 ft from the surface. The tunnel had advanced only four ft beyond the point where work was discontinued years ago when a body of high grade, free-milling gold ore was reached. At present over 100 tons of this ore is in sight, with no appearance of its giving out. The total expense of mining and milling it will be less than $5 per ton; but since it carries an average of $30 per ton, the value of the strike can readily be comprehended. A great revival of mining in the Cable district is looked for.

IN the rolling mills of Pennsylvania there are 2,187 puddling furnaces, and in the rolling mills of the whole country there are 4,463.

THERE are over 67,000 Sunday schools in the country, with an aggregate attendance of 3,000,000 children.

Arizona.—No. 2.

Mining in the Bradshaw Mountains—Tiger District.

About two miles up the trail, easterly from the Tiger is located the Oro Bonito, a gold mine, Mr. W. A. D. Daunes being the superintendent, who very courteously gave us all the information sought, and supplied us abundantly with samples of the ore; in fact such was the case at all the mines we visited with the exception of the Tiger and the Peck. Here, for reasons which we do not understand, we were denied admittance. One would suppose that the Tiger interest might be best served by allowing proper persons at proper times to inspect it; as to the Peck, time and those who control and manipulate it, will tell the story as to its future value as a dividend-paying proposition. They have just erected upon the Oro Bonito property, a Huntington mill, with a crushing capacity of about 10 tons daily. It looks well but has not worked satisfactorily to the superintendent. The ore is in large part a decomposed and honey-combed quartz, carrying free gold and a considerable percentage in silver. They have in the aggregate 368 feet of tunnel. The width of the vein is 18 inches to three feet on the footwall, and on the hanging wall one to two and a half feet. In No. 2 tunnel the vein is three feet wide in the face of the tunnel. Various drifts and winzes have been run in addition to those already mentioned. The cost of wood here is $7 a cord, on a contract, delivered at the mill. Water is obtainable only from the mine at present, and in sufficient quantities to run the works 12 hours a day; but it is expected that as they get in on the tunnel, water in abundance will be found.

To show the difficulty of transportation in these mountains, it is said to have cost some $6,000 to bring the machinery for the Oro Bonito, weighing about 10 tons, from Walnut Grove, a distance of 25 miles. They had to build their road up and over a precipitous divide and down a very steep mountain side into the canyon where the Oro Bonito is located, and where the mountains rise up at a very sharp angle on either side.

Right above the Oro Bonito, on the side of the mountain, is located the Gray Eagle mine. It is well opened and has 500 or 600 tons of ore on the dump. It is free gold, carrying a liberal percentage of silver. It is owned by Mr. Richardson, who has a contract with the Hon. C. C. Bean, owner of the Luke mill in the Bradshaw basin, to pack and crush 300 tons of ore for him at $31 a ton. The ore is now being worked, at that mill, and I predict satisfactory results. He gets his water for the mine from a living spring in the side of the mountain. The mine is approached by a trail from the Oro Bonito, which is almost perpendicular, zigzaging up the side of the mountain, and by another trail, of more recent construction, from Luke's mill in the Bradshaw basin, over which the ore is packed on donkeys from the mine to the mill, a distance of about five miles. This mine has the appearance of being worked by a man who knows his business. Everything is kept snug and in order; no loose ends lying about, and the ore is worked clean to the walls, which are well defined. Mr. Richardson lacks capital to work his mine to the best advantage, and would like to interest some one with him who could furnish the amount of money necessary to enable them to work it so as to obtain the best results. Wood and water are abundant for milling purposes. Pine timber abounds in some parts of the Bradshaw range, especially in the Lynx Creek, Bradshaw, Pine Flat, Hassayampa, and Big Bug districts. The Gray Eagle vein will average three feet wide. It is a continuous, well-defined ledge. They have, I think, three tunnels run in on the ledge at different levels.

The Tiptop mine is about 10 miles across the country over a rough trail from the Gray Eagle. It has produced largely of bullion, but is very expensive to work, and has returned no margin of profit to the stockholders. The regular approach to this mine is by the Black Canyon road and Gillette, where the 10-stamp mill of this company is located, some eight miles from the mine.

There are other mines in this neighborhood, but they are not as well known as those I have named.

W. H. S.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

NOONDAY M. Co.—Object: To mine in Bodie district Capital, $10,000,000. Directors—R. C. Hooker, George R. Root, William J. Taylor, G. A. Holden and William B. Carr.

BONNURANT G. & S. M. Co.—Object: To operate generally. Capital, $2,500,000. Directors—W. B. Ewer, G. C. Fowler, E. T. Bacon, J. O. McCall, A. P. Bacon, G. L. Connor and W. H. Murray.

MONTE CRISTO CON. M. Co.—Object: To operate in Mono county. Capital, $10,000,000. Directors—J. D. Thompson, J. M. McDonald, Clinton Gurnee, L. Shores and B. F. Bevins.

BROPHY M. Co.—Object: To operate in Storey county, Nevada. Capital, $10,000,000. Directors—F. Tagliabue, Victor Fernbach, James M. Wilde, Thomas H. Lawler and George B. Merrill.

STREET & BLANCHE M. Co.—Capital, $10,000,000. Directors—L. L. Robinson, D. F. Verdenal, Thomas Street, F. Tagliabue and Thomas H. Lawler.

ARMSTRONG G. M. Co.—Object: To work in Butte county. Capital, $500,000. Directors—J. S. Rawlins, C. Stevens, P. Amiraux, J. W. Pew and William Armstrong.

High Explosives.

We have received a pamphlet issued by the California Powder Company, manufacturers of Hercules powder, in which is given decisions of the English and United States Courts in the litigation concerning the right to use nitro-glycerine as an explosive when mixed with certain other substances. The Giant Powder Company, owners of the Nobel patents, sued the Hercules Company for infringement on their rights, and there has been a fight between the companies for a long time. The pamphlet in question refers to the whole matter, gives those decisions of the American and English Courts which have been adverse to the Nobel patents, and points out the imperfections of said patents. We have not the space to relate the circumstances of the litigation, but those interested can no doubt procure the pamphlet on application. Suffice it to say, that the California Powder Company continues to manufacture and sell large quantities of Hercules powder, which, judging from the sales, must give satisfaction to the consumers.

The advantages claimed by the manufacturers, in their pamphlet, are as follows:

"Hercules powder is the strongest, safest and most effective of all nitro-glycerine powders. The No. 1 brand has the following composition: Carbonate of magnesia, 23%; nitro-glycerine, 77%. Carbonate of magnesia is by far the best absorbent of nitro-glycerine. Although we add but 77% nitro-glycerine, yet there would be no difficulty in making it absorb 80%, but in order to make our powder perfectly safe we deem it prudent to stop at this point. In addition to the great absorbing power of carbonate of magnesia, it has several other valuable properties.

"1st. The power it has of neutralizing any free acid that may have been left in the nitro-glycerine, thus rendering the powder absolutely safe and not liable to spontaneous decomposition and consequent explosion.

"2d. The uniformity of composition—free from grit or any other inherent quality capable of exploding the powder.

"3d. The carbonate of magnesia itself adds to the strength and power of the powder, since 58% of it becomes converted into the gaseous form during the explosion of the absorbed nitro-glycerine.

"4th. During the explosion of free nitro-glycerine, or nitro-glycerine absorbed by other porous bodies, compounds are formed which cause headache and other serious inconveniences to the workmen. Such is not the case with Hercules, as the carbonate of magnesia neutralizes all such injurious products.

"5th. The uniform character of carbonate of magnesia, which is a chemical preparation, enables us to manufacture a powder having always the same percentage of nitro-glycerine and never over-saturated, thus rendering spontaneous explosions and premature blasts impossible."

NOTES ON BEET SUGAR.—The proposed resuscitation of the Alvarado Beet Sugar works shows that the beet sugar industry in this State has some life, in spite of the many obstacles and hindrances which it has encountered. It may be mentioned also that the subject is reviving in the Eastern States and in the province of Canada, where experiments are being pushed under government patronage. The State of Maine is also enjoying the prospect of profitable production. We find several points of interest in the report of the first season's run in Maine. On the 21st day of October the company began the work of manufacturing sugar from beets, and within nine days after having the first beet go into the machinery, the company turned out all grades of sugars, from standard granulated to common concrete or melado, 94,467 pounds. The quantity of beets consumed to produce this amount of sugar has been 450 tons, and as they were used with tops and even dirt on, many having rotten leaves adhering to them, it must be admitted that the result so far obtained has been fully as good as in the best sugar manufacturing countries, and better than in France. It is one of the peculiarities of the American beet that the heads or leaf-crown contain almost as much sugar as the beet itself, and more than the average beet of France. A drying establishment has been erected in the most northern part of the State of Maine, where the beets have been sliced and kiln-dried preparatory to transporting them to the sugar factory in Portland.

SINCE the United States Supreme Court decision in the Reynolds case, it is estimated that 200 polygamous marriages have taken place in Salt Lake and St. George.

CALIFORNIA, for the first time since her admission to the Union, was unrepresented in the House of Representatives at the opening of the special session.

AT a school district meeting in Washington county, Oregon, the chairman ruled that women are not citizens of the United States.

FIFTY MILLION feet of logs are jammed in the Elk river, near Eureka, Humboldt county, for a distance of eight miles up the stream.

THE London Chamber of Commerce has adopted a resolution in favor of an international agreement for the remonetization of silver.

PATENTS AND INVENTIONS.

Foreign Patents for Pacific Coast Inventors.

The following foreign patents have been issued to residents of this coast:

Canadian.

8,312.—MANUFACTURE OF BUNGS—F. A. Howig, S. F. January 21, 1878.

8,333.—SNOW PLOWS—Geo. Royal, Truckee, Cal. January 22, 1878.

8,353.—CLOCK—W. A. Cates, Union, Ogn. Jan. 26, 1878.

8,457.—PANTALOONS—J. W. Davis, S. F. Feb. 23, 1878.

8,486.—WHEELS FOR VEHICLES—T. H. King, S. F. February 28, 1878.

8,489.—WASHING MACHINE—T. Austin, Virginia City, Nev. March 4, 1878.

8,512.—ANTI-FRICTION BEARING—T. H. King, S. F. March 8, 1878.

8,715.—FRUIT DRIER—W. S. Plummer, Portland, Ogn. April 30, 1878.

8,744.—DEVICE FOR CLEARING SWITCHES—G. Royal, Truckee, Cal. May 2, 1878.

8,994.—SCRUBBING MACHINE—A. F. Stockley, Bishop Creek, Cal. July 10, 1878.

English Patents

Which have passed the great seal:

4,567.—PORTABLE SAWING MACHINE AND TREE FELLER—Wm. H. Smyth, S. F. January 10, 1879.

3,677.—DOOR KNOB—J. F. Peacock and J. J. Zook, Reno, Nevada. February 21, 1879.

German.

4,013.—ADJUSTABLE RAM FOR RAM-BOATS AND SHIPS—D. McColgan, S. F. May 30, 1878.

4,592.—MODIFICATIONS IN BREECH-LOADERS—W. R. Finch, Eureka, Cal., and H. P. Fletcher, S. F. Aug. 17, '78.

News in Brief.

THE plague has reappeared in Russia.

THERE are 7,000 Chinamen in Butte county.

TEXAS papers are praying for the whipping-post.

THE U. S. war-ship *Alaska* has sailed for Alaska.

COMPLETE anarchy prevails at Mandelay in Burmah.

TERRIBLE prairie fires have recently occurred in Kansas.

SITTING BULL is again seriously threatening the border.

THE "dive" nuisance is getting a strong hold on Oakland.

MANY avalanches have recently occurred in Austrian Tyrol.

INDIAN beggars are very troublesome in Lake county, Oregon.

A DEADLOCK is anticipated in the House of Representatives.

TULARE fields do not look green, but the farmers look blue.

ELEVEN HUNDRED Persians have been killed by an earthquake.

THE clam cannery at Puget Sound is doing a profitable business.

THE Rhode Island Legislature has refused suffrage to women.

RUSSIA has adopted a conciliatory line of policy toward Turkey.

THERE is great sickness among the British troops in South Africa.

THE Atlantic sea ports are to be quarantined against the black plague.

TURKEY is threatening Greece and has ordered a man-of-war thither.

GRASSHOPPERS have made their appearance in the Reese River district.

A TORNADO in Georgia recently destroyed $100,000 worth of property.

THE Clearing House banks of New Orleans have temporarily suspended.

IMMIGRATION from California and the East into Arizona is on the increase.

THE electric light is to be employed in the library of the British Museum.

A HEAVY forgery of Dupont-street bonds has come to light in San Francisco.

FOUR cargoes of coolies are crossing the Pacific for the shores of Oregon.

EASTERN oysters are being propagated with some success in San Francisco bay.

RUSSIA is negotiating for the purchase of the Ladrone island, in the North Pacific.

THE necessary repairs on the *Jeannette* for her Arctic expedition will cost $40,000.

THE practice of robbing sluice boxes is becoming quite too frequent around Ione.

CANADA will be held responsible for Sitting Bull's invasion, he being a British subject.

THE furious wind and snow of last week caused considerable damage at Lake Tahoe.

AMERICA is successfully competing with Amsterdam and London in diamond cutting.

AMERICAN meat is about to be imported for the German markets by an English company.

A BILL has been introduced into Congress to remove the political disabilities of Jeff. Davis.

PIKE are caught in Putah creek that weigh as high as seven pounds, and the creek is full of them still.

A LARGE land slide occurred last week at the southern opening of tunnel No. 3, South Pacific railroad.

THERE seems to be no possibility of indncing an English University crew to row in the United States this summer.

THE Memphis cotton and woolen mills were struck by lightning on the 22d and totally destroyed. Loss, $90,000.

THE Monterey Whaling Co. captured a fine hull whale on the 23d, of the California gray species, after an exciting chase.

THE citizens of Cacheville have got rid of the Chinese by the owners of the premises in which they lived pulling down their shanties.

Bullion Shipments.

Since our last issne, we have noticed the following bullion shipments:

Bodie, March 17th, $5,272.78; Ophir, March 18th, $20,923.15; Northern Belle, March 19th, $6,916.01; Standard, March 20th, $19,568.68; Bulwer, March 20th, $17,495.40; Paradise Valley, March 20th, $2,288.68; Alexander, March 21st, $12,743; California, March 22d, $82,828.98; Northern Belle, March 22d, $12,004.62; Con. Virginia, March 22d, $74,688.75; Paradise Valley, March 22d, $3,259.59; Independence, March 24th, $6,700; Grand Prize, March 24th, $4,700; Christy, March 25th, $5,995; Manhattan, March 21st, $11,461.

THE regular government of Sonora, under Mariscal, has been overthrown by Serna. The forces of the general government aided the revolutionists.

THE Russian Nihilists have killed a government spy and attempted the life of a chief of the gendarmes.

THE Oregon & California Stage Company had six horses drowned in a slough near Canyonville recently.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by *letter*.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurauce Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

CAPITAL CLOTHING.—One of the proprietors of this journal having for six months past worn a gray suit manufactured by the Capital Woolen Mills, Sacramento, we can now speak in high praise of the wearing qualities of their goods and manufacture. Also of their prices. Try them

M. D. SHRADER is now an authorized agent of the PACIFIC RURAL PRESS, also MINING AND SCIENTIFIC PRESS, to solicit subscriptions and receive the money for the same His receipts given for such money will be duly honored by this company.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. Sec ad. F. W. FULLER, 415 Market St., second floor, S. F.

Fine Engraving.

The Engraving Bureau belonging to the office of this journal is prepared to design and engrave all kinds of WOOD CUTS for illustrating newspapers, books, catalogues, cards, circulars, advertisements, labels, badges, seals, etc., in the best style of the art. Our portraits and illustrations of machinery, buildings and landscapes, are superior. Good engravings can be made from paintings, lithographs, steel and copper plate prints, photographs, models, patent office or other drawings. We have a photographic department and the best of machinery for producing accurate and perfect work at the lowest prices. Original maps, charts, and diagrams are made by our NEW PHOTO-RELIEF PROCESS at greatly reduced rates. By the same process copies can be cheaply and quickly produced of printed cuts, in *fac simile*, or they can be enlarged or reduced with equal facility.

Any hand writing in perfectly black ink on clear white paper for manuscript letters or circulars, will be accurately reproduced in metal plates suitable for common printing. Also, *fac simile* signatures, monograms, sheet music, etc. We excel in trade cuts and matched plates for combination color printing. With a large business, long established, and every facility for improvement, we can guarantee more than ordinary satisfaction to all of our patrons. All interested are invited to send for or call and see specimens and obtain prices.

Orders for electrotypes, stereotypes, steel and copper plates, lithographing, stamps and seal presses executed at low rates.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1879.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 130 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, $7.50.

President.

Fuse Lighter and Fuse.

COL. SAM'L O. GREGORY,
Secretary.

Safety Cap and Fuse.

Electric Cap.

Safety Powder, Caps, Electric Caps, and Fuse Lighters.

Under a series of U. S. Patents, after long and carefully conducted experiments and thousands of tests, this Company is prepared to manufacture and supply, for Mining and Engineering Works, the above named articles at prices and on terms as favorable as articles of similar grades are now supplied in this market. Our Powders contain no Nitro-glycerine, no Nitroline, no Gun Cotton, no Fulminates, and are free from the unavoidable dangers in manufacturing transporting, handling and using of all high grade explosives which contain those elements.

Cold does not affect them. They cause no headaches or other inconveniences in handling, and the smoke from their explosion contains no poisoning or sickening vapors.

Their blasting force, with slight tamping, at least equals that of any Powders now used, but they admit and require strong tamping to bring out their immense and peculiar lifting power which follows their detonating work. They should be fired, therefore, by our

Safety Cap,

Which allows tamping without danger. They can be fired by any caps now employed in blasting, but the use of these is always dangerous with any Powder, and the loss of the throwing power resulting from lack of tamping renders it with our Powders doubly objectionable.

Our SAFETY CAPS have twice or thrice the force of triple Giant Caps. When set on fire they do not explode, but merely burn off, and are perfectly safe in transporting and in tamping.

In round tin boxes, 50 cents.

The Safety Fuse Lighter,

Cheap, handy and sure to light the Fuse upon the end of which it is fastened, only needs a trial to be appreciated by every miner who is up to "snuffs." 25 Cents per box; sent by mail.

Safety Fuse,

Equal to the best in the market, will be supplied at the lowest market prices.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature, thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

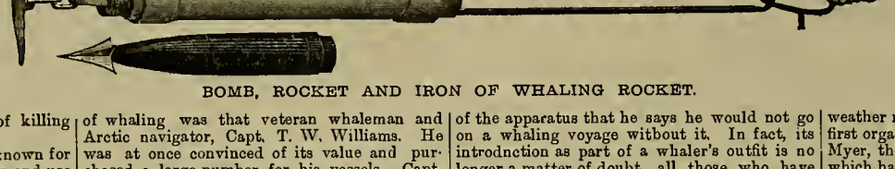
SAN FRANCISCO, SATURDAY, APRIL 5, 1879.

VOLUME XXXVIII Number 14.

The Roys and Liliendahl Whaling Rocket.

Although the idea of killing whales by means of bombs or rockets is by no meaus a new one, it is only very recently that the plan has been successfully carried out with any practical results. The Roys and Liliendahl whaling rocket, views of whicb are given herewith, is an ingenious application of the rocket prinoiple for propelling an immense bomb-lance with an enclosed loggle or harpoon attachment, and is capable of carrying a three-incb rope, or the ordinary whale line, with equal facility. The manufacturers of this weapon contend that it is the most destructive implement ever devised for the purpose of killing whales.



BOMB, ROCKET AND IRON OF WHALING ROCKET.

The Roys whaling rocket has been known for a number of years, but its introduction and use bave not been successful, for the reason that the defects in construction operated against its efficiency. It was used on this coast, with some measure of success, in different localities. Messrs. J. N. Fletcber and R. L. Suits, 407 Front street, San Francisco, owners of patent rights for this coast, experimented witb the rocket for some time in order to test it and find out the defects, knowing the principle was good. They found that it had been previously made too light, and that there was not powder enough in it. Moreover, in order to make it cheap, the details of the construction had not been carefully worked out. They have improved upon the rocket, made it heavier and stronger, and finally made a practical thing of it. Its defects have been entirely eradicated, so that notwithstanding the great weight of the projectile, which is about 32 pounds, it can be almost as easily handled as an ordinary bomb-gnn; and what is particularly noticeable, can be forced without detriment to tbe shoulder.

KILLING WHALE WITH THE ROYS AND LILIENDAHL WHALING ROCKET.

The apparatus consists of a strong brass cylinder containing the projectile charge. This is loaded with a peculiar powder, made by Fletcher & Suits themselves. In the front of this is secured a bomb containing an explosive charge, and inside of it is a harpoon attached to the shell. An iron is secured to the rear end of the rocket, to which is attached the whale line. The bomb has a bearded or barbed point, and when projected into the whale by the rocket, explodes, inflicting a fatal wound. At the same time tbe harpoon takes its hold, and the boat is fastened to the whale by the line attached to the iron. These shots are good for killing and fastening to a whale at 30 fathoms distance, which is, of course, very much further than an ordinary harpoon is available. The whole apparatus weighs 32 pounds, and from the point of the bomb to rear end of iron is six feet six inches in lengtb.

A peculiar rest is used in firing the rocket, having on it a shield to protect the operator from the fire which issues from the rear end of the rocket. The rocket is set in the rest, the rear end of wbich is placed on the shoulder, and by discharging a pistol charge into a hole provided for the purpose—after aim is taken—the projectile is discharged and the rocket powder carries the rocket, bomb and line in the direction required. The construction and operation will be clearly seen from the accompanying engravings. The line is placed in the usual tub in the boat coming down forward of the standard, as will be seen by the cut. As there is absolutely no recoil, tbe rocket can be used from boats of light construction, as well as from steam launches or heavy boats.

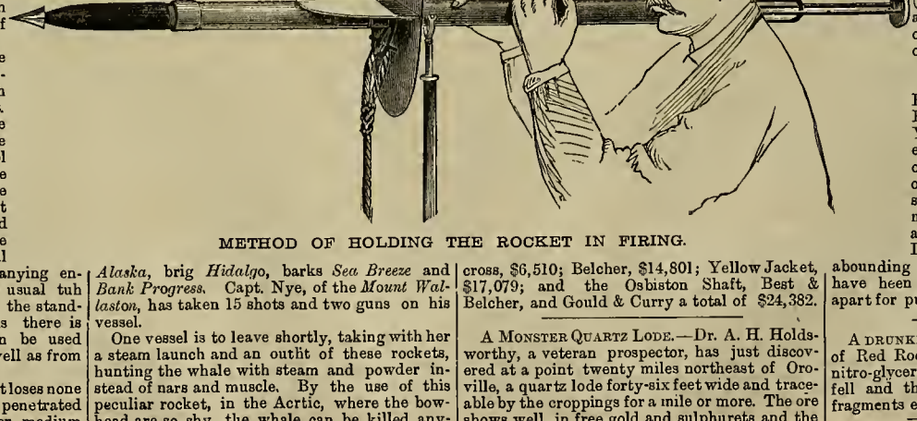
Another advantage is that this shot loses none of its force or velncity when it has penetrated the water, as the gas having a denser medium to react upon, propels the shot witb the same velocity that it wonld through the air.

The manufacturers have, at various times during tbo nast winter, given exhibitions of the practical working of this weapon, and the masters of whaling vessels have been so favorably impressed with it that almost the entire fleet sailing from or visiting this port are now armed with it as part of their outfit.

Among the first to look into this new method of whaling was that veteran whaleman and Arctic navigator, Capt. T. W. Williams. He was at once convinced of its value and purchased a large number for his vessels. Capt. Cogan, of the bark *Rainbow*, and inventor of the Cogan breech-loading homb-gun, having seen some of these shots fired, was so favorably impressed that he ordered a number of them for his vessel. Capt. Owens, of the *Coral*, has also armed his vessel with them, and will no doubt give a good account of them when he returns from the Arctic. Capt. Smith, of the steam brig *Siberia*, is also plentifully supplied. Capt. Canghell, of the schooner *Newton Booth*, has heen using these rockets down the coast so successfully that he has telegraphed for a new supply of shots. Among other vessels which have them we may mention the schooners *Leo* and *Alaska*, brig *Hidalgo*, barks *Sea Breeze* and *Bank Progress*. Capt. Nye, of the *Mount Wallaston*, has taken 15 shots and two guns on his vessel.

One vessel is to leave shortly, taking with her a steam launch and an outbt of these rockets, hunting the whale with steam and powder instead of nars and muscle. By the use of this peculiar rocket, in the Acrtic, where the bowhead are so shy, the whale can be killed anywhere within a distance of 30 fathoms, while in the old-fashioned way it is very difficult to get near enough to them to kill. Very little practice will onable anyone to shoot the rocket very accurately, and wherever it strikes it kills, no whale getting away when struck. Messrs. Fletcher & Suits have acquired the right of manufacture and sale of these rockets for this market. Capt. Williams, an owner of three whaling vessels, is so convinced of the efficiency of the apparatus that he says he would not go on a whaling voyage witbout it. In fact, its introdnction as part of a whaler's outfit is no longer a matter of doubt, all those who have used it speaking highly of the apparatus.

The bark *Legal Tender*, whicb goes up to the Arctic in June to bring back oil from the fleet, will take up a number of guns and shots for the whalers which are not already provided witb them; and will also supply additional shots to all who want them.



METHOD OF HOLDING THE ROCKET IN FIRING.

PAY ROLLS.—The men employed in some of the leading mines on the Comstock received their monthly wages a day or two since. The amounts disbursed by these several companies were as follows: Savage, $9,224; Hale & Norcross, $6,510; Belcher, $14,801; Yellow Jacket, $17,079; and the Osbiston Shaft, Best & Belcher, and Gould & Curry a total of $24,382.

A MONSTER QUARTZ LODE.—Dr. A. H. Holdsworthy, a veteran prospector, has just discovered at a point twenty miles northeast of Oroville, a quartz lode forty-six feet wide and traceable by the croppings for a mile or more. The ore shows well in free gold and sulphurets and the find is considered one of great value.

International Meteorology.

We printed last week an item calling for the extension of the work of the Signal Service so that daily observations could be exchanged between all the leading points nf the world by telegraph. It seems that events are gradnally tending toward this result and tbrough direct efforts of our own Signal Service wbich has pressed the subject upon the attention of other nations. The permanent committee of the Vienna Meteorological Congress have just paid the United States the high compliment of recommending to a proposed second congress the adoption throughout the world of a plan for exchanges of data for simultaneous weather maps or other purposes, similar to one first organized for the United States by Gen. Myer, the Chief Signal Officer, in 1873, and which has been continuously pursued by the Signal Service to this day.

The features of this exchange, as set on foot by the United States, are as follows: 1st. Tbe Signal Office of the United States asks all countries to make and record daily, on land and sea, one simultaneous weather observation at the same exact instant of time. 2d. The United States then exchanges with each country separately, making an especial request nf each to establish such exchange. 3d. Each country sends to the United States every 15 days its own observations; all are thus received by the United States. 4th. The Signal Office of the United States then collates and prints all, its co-incident observations iucluded, and returns in this shape to every regular obser ver, who has sent contiuuously a single report, the reports gathered from almost the whole northern hemisphere. For one report sent regularly hy any regular observer anywhere, on ship or shore, he receives 500, and these 500 surround and cover nearly the northern hemisphere. It has heen the theory of the Chief Signal Officer that, with such information so widely diffused, a great deal of work will be done by separate observers in every country which will he of use to all, but which the solitary observer alone could never tbink of undertaking unless the data have been thus laid down before him. The United States need the data for themselves, and they help besides an international union of brains as well as hands.

For nearly six years this exchange, originated and conducted hy the Signal Service of the United States, has been perfectly successful, almost every civilized nation north of the equator has taken part in it. It bas made possible for the first time in the history of the world tbe preparation of a daily simultaneous map of the northern hemisphere, at Washington (this also is sent to each observer), and has probably advanced the study of practical meteorology as far as any one undertaking in the last century.

WONDERS OF THE YELLOWSTONE REGION.—According to the report of P. W. Norris, Superintendent of the Yellowstone National Park, there exists in that district a mountain of obsidian or volcanic glass. It stands on the border of an immense boiling spring, whence it arises in high masses, the surface so smooth that an Indian could not climh up it. It is well that a tract nf country so abounding in strange natural curiosities should have been reserved from settlement and set apart for public nses.

A DRUNKEN man staggered through the streets of Red Rock, Penn., carrying eight pounds of nitro-glycerine in a bag on his hack. He finally fell and the resulting explosion did not leave fragments enough of him to bury.

THE Sonora revolution is practically ended.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Notes from Virginia City.

Editors Press:—The long-pending compromise hetween the mining companies and the Sutro Tunnel Company has at last been consummated, hut the henehts to he derived by the mining companies, in the way of drainage, will he delayed for some months to the all mines not situated near the line of the tunnel. The first to take advantage of it will he the Savage, Hale & Norcross, and Chollar Potosi. The others, hoth north and south of the tunnel, will have to wait nntil the lateral tunnels reaches them. The tunneling north aud south I do not think can hs commenced until the sub-drain is completed, and the hoxes iu place and covered, and track relayed. But the fact being established that there is to he no more talk and skirmishing hetween the mining companies and the tunnel company, and that the former have heen compelled to acknowledge that they cannot well get along without the use of the tunnel, will have a tsndency to give people more coufidence for the fnture of the mines, and will also make it more certain that a great number of men now ont of employment will find work in the tunnel and mines. Of course some time must elapse hefore the full benefit of the settlement will be realized, hut the uncertainty as to the result of negotiations hetween the contending parties is now done away with, and we must now wait for the henefits to accrue.

The probahility of the adoption of the new Constitution in California is used extensively hy the "hears" to press down stocks to the lowest figures possihle, and the game is succeeding to a charm. It seems that it has but lately hecome apparent to the hrokers of San Francisco that if the new Constitution is adopted their business will he ruined, and that the gambling that they are now engaged in will come to an end, and that they will be compelled to seek some other field for the exercise of their geniuses. I am inclined to think that the adoption or rejection of the new Constitution will not effect the business of mining, and that the cry is used now to make a grand smash in "securities," and that the same brokers who say that their business will be ruined if it is adopted are only doing so to speculate on the credulity of the masses. They have now about six weeks in which to stock the cards and prepare to draw the four aces when the time comes for them to show their hands. If that new Constitution is to be so ruinous if adopted, why has it not been found out hefore this? The fact has not been discovered until lately.

The yield of bullion from the Con. Virginia for this month, so far, has been in excess of that of last month to this time, and there seems to be some probahility that a dividend will he declared for the month of March. It will require two or three months before Sierra Nevada will be in readiness to commence tbe extraction of ore. The North Con. Virginia shaft has reached the 1700 level of the south drift of the Sierra Nevada, and the east shaft has been connected with the drift from the incline on the 2200 level, which connection has improved the ventilation in the lower levels of the mine greatly, and will enable the work of opening up the mine to be proceeded with much more rapidity. The incline has reached the 2400 level, hnt whether a station will he cut out there and a crosseut run west into the ore body, or drift be run north and south and the incline extended to a further depth, is not known to outsiders.

The Leviathan company have nearly completed the repairs of damage to their cage and car (occasioned by the breaking of the cable and dropping them some 400 feet, to the hottom of the shaft) and obtained new cahles. They will he in readiness to start up again in a few days, when I believe it is the intention to commence crosscutting on the nortb 750 level drift, east and west, which must, from all indications, bring them into ore. It is said to be the intention of the Con. Virginia and California companies to run a joint drift west on the 850 level. If they do tbat, the probability is that they will go far enough west to be in the ground originally helonging to the companies from which Con. Virginia and California were formed. It is a well-known fact that the bonanzas which they discovered, and have heen working out, had nothing to do with those mines as originally located. Those companies went far to the east and sunk their shaft into separate and distinct bodies of ore from tbat belonging to the so-called Comstock lode. As the original locators of east ore hodies had not the means with which to contend for them, they appropriated them, as they will continue to do if they find any still farther east, although they may have to drift through hundreds of feet of syenite rock to reach them. This aggressiveness on the rights of others, practiced hy the Comstockers, has heen a very nnjust thing, but on the principle on which they act, that might makes right, the weaker party have had to succumb. I shall have more to say on this subject at another time.

J. D.

Virginia City, Mar. 25th.

Mining Notes from Siskiyou County.

Editors Press:—The miners are generally hard at work, I believe—at least all the creeks and old Scott river show the effects of mining in their muddy waters. We have some encouraging reports from our quartz mines; extra good prospects and some big honauzas are reported. One of my neighhors, Mr. H. C. Cory, informs me that they have struck a good prospect, to say the least, in one of their tunnels on French creek. They think it will average $30 per ton. I hope it may last, and prove to be, indeed, a perfect honanza.

I am of the opinion that there are good mines in this neighborhood, and that the near future will prove them to bs so. The main drawhack heretofore has heen, that the parties trying to develop these mines were farmers, with work enough at home in the dairy and on the farms to occupy their time and require their whole attention; and also they were lacking in cash. This latter article we all know to he very essential in mining. It is true that here, at home, these mines are generally considered helow par, hut what of that? If their owners are said to he fanatics on the mining question, the claims (for they are really nothing hetter, never having heeu developed into mines yet, strictly speaking,) prospect well, and although they have heen prospected for a numher of years, and a large amount of hard lahor, hesides a considerahle quantity of money has heen expended upon them, yet not judiciously. An inexperienced man cannot do as mnch in this line with a year's work and $1,000 cash, as a competent man of experience can do, or accomplish, with one-third as much.

John Daggett worked a long time, met with every discouragement, yet struck a honanza at last, and one that seems likely to last. So, too, the Quartz Valley mines, Dick Johnson and many others, are only ahout 15 miles northwest of here. They prospected and worked for years in the face of every opposition. and though their neighbors and other "knowing ones" cried "hust," "no account," etc., yet to-day, after the mines are open, they are proving successes, some of them grand, excelling the most sanguine expectations of the owners. I promised Mr. Cory that I would visit his mines soon, and write what I may see with my own eyes. I do not helieve in exaggerating or "stretching the hlanket" too far; it has caused more injury than it accomplishes good. I could find items enough to send in, to fill the whole of the Press, but I don't wish to place anything over my name that I am doubtful about, or that I believe to he false: I had rather say less and be sure of the correctness of that little. There is one thing I do think, and that is, that this county is destined to stand high among the mining countics of the State at no very future day. We need men of capital and experience, comhined with industry and ambitiou. I think the Press should he better patronized by the people, and truthful accounts and items handed in to the different local and traveling correspondents—everything of interest, in fact, for publication. I am sure we will, any of us, take the time to write them up.

R. D. Nunnaly.

Etna Mills, March 3d.

Renewal of Files by the Sand-Blast.—Notwithstanding the doubts which have been thrown out in regard to the practicability of re-sharpening files by the use of the sand-hlast, the application of the principle seems to he giving good satisfaction in Europe, if we may give credence to the following paragraph, which we clip from the *La Gaceta Industrial:* "The application of Tilgbman's sand-blast to the restoration of worn-out files, is hecoming very general in Europe. A file of moderate dimensions requires only three or four minutes for renovatiug. The process can be repeated many times hefore the files need to he recut, and tbe sand-hlast sharpening lasts six times as long as any other. The sand should he very fine and driven with great velocity."

Modified form of Locomotive Boiler.—Mr. Verderber, of the Hungarian State railways, has made some interesting experiments with a modified form of locomotive hoiler, as a means of avoiding the expense of frequent repairs of the fire-box of the locomotives used hy him, which were rapidly destroyed in consequence of sediment from bad feed water. He found by actual comparative trials that the fire-box is superfluous as a steam-generating part of the hoiler. He found it possihle, therefore, to replace the fire-hox hy a comhustion chamber lined with fire-proof material.

Heat on Wrought Iron and Steel.—It is said that the effect of heat on steel is quite different from that on wrought iron. If a piece of cast steel be made red-hot and is quenched in cold water it will become longer, but if the same operation he performed upon a piece of wrought iron it will hecome shorter. The precise amount of the alteration, or its variation in different qualities of each metal, has never heen determined, although it is of great importance in work-shop manipulations.

Forest Preservation on the Pacific Coast.

That we have not ignored nor seemed indifferent to the importance of duly guarding the timber lands of Californuia, and, indeed, of the entire Pacific coast, from unnecessary waste, ws need not assure the readers of the Press. That we have ever hesn alivs to the momsntous character of this question, discussing it with fulness and an appreciative sense of its magnitude, our columns amply attest.

Sir J. D. Hooker, the distinguished English hotanist, who visited this coast last year, has since his return home written a letter to Mr. Gray, one of the Yosemite Commissioners, giving it as his opinion that the most disastrous consequences must follow the destruction of the forests in this State, aud throughout the great interior basin lying to the east of us. The ahility to continue the production of our fruit and cereal crops depends, says this eminent scientist, upon au ahundant and uninterrupted water supply, which in turn is contingent upon the conservation of our redwood forests near the sea coast and those on the western slopes of the Sierra Nevada. The destruction of these forests in whole or in large part will suhject the State alternately to disastrous floods, and still more disastrous drouths, to say nothing of timber supplies cut off. In taking measures to guard against these dire results it will not suffice that the trees over small areas are preserved if the great hody of the forests themselves are destroyed. Unprotected from the elements these small patches would become the prey of parasites, he attacked hy disease and perish also in the end. As a preventive measure, this gentleman suggests the adoption of a system of forest-felling hy selection, the same to he placed under State supervision, after the plan adopted hy the English government in India and elsewhere.

Prof. Sargent, Director of the Botanic Garden of Harvard Uuiversity, puhlishes in the *Nation* a still more extended article on this suhject, copied in our last issue, and to which we need hut refer the reader. Emauating from such authoritative sources, and coming to us in this shape of hoth a protest and appeal, these statements of Sir J. D. Hooker and Prof. Sargent command our earnest attention, and we should see to it that the government, both State and National, take early action for averting these predicted calamities. As yet the title to most of our forests lands remains in the general government.

While the destruction of timher on this coast has been rapid and sufficiently wanton, it has not been so great perhaps nor so criminally wasteful as many suppose. Our cities and towns, mostly constructed of wood, have, through many conflagratious. beeu compelled to a frequent rehuilding. In San Francisco street and sidewalk planking, hlock paving and wharf huilding bave heretofore consumed much lumber; more a good deal than will probably be required for these purposes in the future. In the mining districts buildings of nearly every description have from the first been made of wood, those erected in the earlier days being mostly composed of logs and shakes, the latter a very wasteful mode of employing lumher to such end, and one that has led to generally exaggerated notions as to the reckless habits of the primitive miners and lumbermen in this particular. These shakes, a long thick style of shingle, split from the sugar pine, abont the most valuable wood that grows in our California forests, were used for both covering and enclosing huildings. Now it was the practice with these men, if after felling a tree it did not split well, to leave the same and cut down another, so keeping on until they found one to suit them. The sight of these noble trees so left to rot where they fell excited afterwards an amount of indignant comment that caused many to think they had been destroyed through sheer wantonness. And one of these old-fashioned log cabins took timher enough if sawed into hoards to build two or three good-sized houses. The use of iron pipes instead of lumher for flumes, and of worn-out rails instead of blocks for paving sluices, to say nothing of the much more general substitution of iron and other material for wood, must hereafter everywhere tend to diminish the consumption of the latter, lessening to that extent these drafts upon our California forests.

But the great objection to cutting dowu the forests in this State is not based so much upon a prospective scarcity of lumber as upon the injury it will work our agricultural, mining and other great industries. In the woods of Oregon, Washington Territory and British Columbia, to say nothing of Alaska, we have timher preserves that, even with the heavy demands heing made upon them, must last for a long time to come. So great are our lumher resources in that direction, that they require no supervising care for the present. Nor here in California would precautionary measures become so necessary were it not that the tendency of the forests to reproduce themselves is likely to he suhverted by the herds of browsing animals turned out upon them, and which threaten to so increase that but few young trees will he spared hereafter.

Along the main timber belt of the Sierra where the forests have heen removed the young conifers spring up and, if not eaten off, grow with great rapidity and vigor. They will do so even in spite of the presence of neat cattle, horses, swine, etc., but it is doubtful if they can withstand the depredations of the sheep, to say nothing of the still more predatory and voracious goat, with which animals ths westerly slopes of the Sierra ars beginning to he thickly covered. It is the opinion of many close observers that there will he left not the slightest chance for these forests to renew themselves if either sheep or goats are permitted to pasture among them in large numhers. However this may be, such regrowth seems possihle whers only other kinds of stock are suffered to feed on these denuded forest lands. In support of this opinion the evidence is ample, trees of new growth stauding thick aronnd some of the oldest mining camps, and even in the vicinity of populous towns all ovsr this region. Take for example tbe country ahout Nevada City and Grass Valley, two of the earliest sattled as they are now the largest towns in the mining districts. These places are some five miles apart, and yet much of the land around and even right between them is covered with groves of splendid young pines, some of them a foot or more through at the hutt and from sixty to eighty feet high. No care has beeu taken to prevent stock of any kind from feeding on this land, the most of which lies in common, the trees on the enclosed and unenclosed portions appearing to have flourished alike. It is now about 20 ycars since the original growth of timber here hegan first to be cut away, the life of these new groves averaging about 20 years. As they stand very thick on the ground these groves, which already require thinning out, would afford a great deal of fuel, as in another 20 years they will afford suitable material for making lumher.

What is true of the land in the neighborhood of the towns here instanced, is true of the entire westeru declivity of the Sierra above and below certain levels. In the lower foothills and to an altitude of about 1,000 feet, the timber growth is confiued mostly to oak and two spscies of pine, the *Pinus contorta*, twisted pine, and the *Pinus sabianiana*, a scruhby nut-hearing tree, popularly known as the "Digger" or "Bull" pine. Once the first growth is hsre cut away the process of self-planting goes on not again or does so very slowly, this heing the case also as we approach the upper timber line, which in these mountains varies in hight from 9,000 to 11,000 feet. Throughout the whols intermediate space, however, along the west face of this range, a belt varying from 50 to 100 miles across and some 500 miles in length, ths young trees, upon the removal of the old stock, sprout up and grow in the most thrifty manner, as they will continue to do, no doubt, if protected from the ravages of domestic animals, and perhaps also without such protection, observers not being agreed on this point. If sheep are so destructive to the young trees as some have feared, it is a little singular that ths new growth should have made such progress in these early settled and populous neighborhoods, where many of these animals must have heen kept if for no other purpose thau the shambles, and where as is well known no care has been taken to keep them off these land. However this may he, certain it is that Nature, if we give her a fair chance, will do ths replanting here and bring forward the new crop of spruce, cedar and pine without any aid or supervision on the part of man. But we must see to it that she is not defeated in her beneficent and self-imposed task. It will he to little purpose she essays the practice of her forestry if we carelessly neglect to second her efforts or criminally interfere to defeat them. If it shall be found that sheep and goats or any other class of animals are likely to destroy the young trees or in any way prove detrimental to their growth, thcre would have to bs measures adopted to regulate the matter.

In the great interior valleys of California tres culture has begun, and will soon reach such dimensions as will more than repair any damags they may have sustained through the cutting down of the primitive growth of timher thers, which never was great. As for the State of Nevada and most other parts of the great basin, their timher growth is too sparse and stunted to he worth considering in this connection. From the eastern base of the Sierra Nevada to the Wasatch range, a distance of 600 miles, ths only trees to be found, excepting a few worthless cottonwoods along some of the rivers, consist of a species of scrubby pine and juniper scattered sparsely along the mountain sides, with here and there a grove of white pine, also a scrubby sort of tree but large enough to make a poor kind of lumber. To talk of preserving these trees where there exist such stringent necessities for their use, or to consider them with reference to their climatic effects, would he idle. Without using this timber, poor as it is, the mines could not he worked, while it is altogether too stunted and sparse to exercise any appreciable influence upon the rainfall or other meteorological feature of the country. For the puhlic authorities to attempt any interference looking to its preservation would he useless; all that should he attempted in that direction being to experiment with a view to finding the species of tree best adapted for culture in these arid mountains, valleys and widspread plains, and, when found, to plaut it as extensively as possible.

Telegraphing to Running Trains.—C. M. Gariel describes the successful working of Baillehache's invention for signalling to and from trains in motion, on a part of the line which connects the Champs de Mars with the station at Grenelle. The experimeuts were so successful that they are likely soou to be repeated on a much larger scale.—*La Nature.*

MECHANICAL PROGRESS.

Two Great Fairs.

There are two great international exhibitions approaching which should receive the attention of Pacific coast manufacturers and producers. The countries now preparing for them lie near this coast, commercially speaking, and to make a good impression upon those engaged in developing the resources of those countries, will go a good way toward securing a profitable trade for the manufactures which are made best on this coast. The influence of large industrial expositions upon the development of export trade is much more widely recognized now than before the holding of our centennial display at Philadelphia. Exhibitors at that exposition have heard from the uttermost parts of the earth, and American machines and manufactured articles have secured introduction in many countries which before had thought that only England and the Continent of Europe could supply their needs. Among other countries which had their eyes opened to the desirability of American manufactures was Australia, and the disposition of favor toward our manufacturers is now quite prevalent in the island colonies. California will share largely in this feeling. In fact the Australians keep a sharp eye on the progress of industrial methods and appliances on this coast, that they too may profit by any real improvement which may be made here. Nor are other classes of machinery neglected. We read the other day that one of the Australian colonies had appointed a commissioner to come to this coast and study the boring of artesian wells, and purchase an outfit of the best tools, for use there on experiments under the auspices of the government. These are but few of the many indications that there may be a great future for trade in our productions with Australia—a trade which has already reached respectable proportions in some lines of produce and merchandise.

These facts naturally lead to mention of the Australian International exhibition which will be opened in Sydney, in August or September next. The managers invite the fullest exhibition of Pacific coast products. An acre of space has been set apart for the United States. No charge will be made for space, and if early notice is given motive power will be supplied. The preparations for the exposition are going forward rapidly and on a liberal scale, the drawings of the buildings which we have seen, representing imposing and well planned structures. There is a point which will restrict exhibitions from this coast, and that will be the high rates of freight prevailing, but it would certainly seem to the interest of carrying companies to remove this obstacle or reduce it as much as possible, because displays of articles suited to local needs in Australia will lead to many shipments in the near future. It is a project in the realization of which these companies will share largely in the benefits and a liberal policy would seem wise.

Another international exposition which we would mention is one planned by the Mexican republic, and to be held in the City of Mexico in 1880. The Mexican republic has suffered severely during the last few years by various reverses. The distinguished Minister of the Interior, Riva Palacio, in his circulars announcing the exhibition, remarks that in harmony with the opinion of many distinguished citizens, the Mexican Executive believes that the origin of the greater evils which, until now, the country suffers is an economical, rather than a political one, and that in order to check those evils, not only are the patriotic efforts of the good sons of Mexico required, but also the effective concurrence of foreign intelligence and capital.

The Executive believes that an international exhibition—the most proper means of bringing together the intelligent and enterprising men of all nations—must be favorable, by this mere fact, to the realization of the ends indicated. Foreign exhibitors, as well as those of the Mexican States, will be free to exhibit their articles in the buildings or pavilion raised by the governments of their respective nations or States, or in the common building for the exhibition, as it may suit their interests. The governments that maintain relations with that of the republic will be respectfully invited to send special commissioners to the exhibition. In due time the ports of entry for objects destined to the exhibition will be determined. These objects, in accordance with the regulations that the Department of Finance will duly issue, shall pay no duties, except in case of sale, and may remain exposed six months exempt from all local or warehouse charges. The Managing Committee will shortly publish in the Italian, English, French and German languages, and with the approval of this department, the necessary regulations for carrying out the exhibition in the most advantageous manner to the exhibitors and to the republic.

This is also a movement in which the Pacific coast States and Territories can with profit take a share, for if Mexican production, trade and progress revive, we shall be in the way to share its benefits. We have one of the most commanding commercial positions in the world, geographically; we should see to it that our advantages are employed to their fullest extent.

A Gigantic Ocean Steamer.

Ocean travel has not met with any important changes or improvements since the first introduction of large sea-going steamers. There has been no great improvement either in the mode of construction, speed or comfort of passengers on ocean steamers, since the establishment of the Cunard line between New York and Liverpool. But it cannot be supposed that in an age of invention, such as this in which we are now living, ocean travel must be the only exception to progress and improvement. At least this has been the opinion of one enterprising family—the Winans family, of Baltimore. Most of our readers have had more or less knowledge that for the last twenty years or more, the Winans brothers have been engaged in experiments on a most costly scale, looking to an important advance in the construction of ocean steamers for rapid transit.

Possessed of almost unlimited means and of the highest order of inventive and constructive genius, these gentlemen have never lost sight of this one object, and the public is now assured that they are about to enter practically upon their new mode of steamer construction. They have expended already over $3,000,000 in experiments alone, without receiving a dollar in return. So exhaustive and complete have been these experiments, and so well assured are they of success that the first steamer which they will build will be upon the most gigantic scale—far exceeding the dimensions of the *Great Eastern*.

One of the chief features of novelty in the Winaus' steamer will be its cigar-shaped hull, which will be 1,200 feet in length—508 feet longer than the *Great Eastern*. It will have engines of 100,000 horse-power, and will be propelled by two screws under the after quarter of the vessel. The average speed, based upon most extensive practical experiments, and the most thorough scientific calculation, will be 23 miles an hour.

Another important and novel feature will be a tower 150 feet high, containing in part staterooms looking out on circular balconies, but having within a hollow cylinder vertically throughout its entire length and traversed by an immense weight susceptible of being adjusted at any desired hight. The effect that this tower produces upon the motion of the vessel is precisely the reverse of that which one would most readily infer. When "scaled" to a proper hight, in proportion to the "beat" or motion of the waves prevailing, it absolutely prevents all rolling. The great length of this steamer will prevent pitching, so that, presuming it justifies the claims and expectations of the inventors, it should be very advantageous for purposes of ocean travel. It is designed for the trans-Atlantic mail and passengor service, and their port of entry in this country will be New London, Conn., of which a special survey was made three years ago with this view. Milford Haven is expected to be the port of entry for Great Britain.

That it will revolutionize ocean travel is the conviction of the Messrs. Winans, and on that conviction they have expended millions, and are about to expend still more, it being their intention to construct three other similar vessels as soon as that described shall have been successfully operated. The estimated cost of construction of these vessels is £1,000,000 sterling each, and it is confidently believed by the Messrs. Winans and many of their friends, that they will accomplish the passage of the Atlantic in less than six days at all seasons, and in spite of any weather which has been known as yet on that ocean.

New Light on Steel Making.

It would seem that the presence of more than one or two-tenths per cent. of phosphorus in pig iron is no longer to be considered, as heretofore, an insuperable obstacle to its conversion into ingot steel. It has been fully established that as much as 0.32% of phosphorus can be tolerated in very mild steel, and, as it is well known, large quantities of Martin steel made from old iron rails and pure pig have, by the aid of ferro-manganese, been manufactured on this principle. The difference between the cost of changing old iron rails, and that of using pure materials, is, however, in most localities not sufficient to cover the extra expense of using ferro-manganese.

It remained, however, an axiom with steel makers, that no removal of phosphorus could be hoped for in any direct steel process till it was announced from the Blaenavon iron works that there were means by which phosphorus could be removed with certainty and economy, and that intensity of temperature was no obstacle to its removal. In confirmation of the Blaenavon experiments, we learn that very important results have been obtained in Belgium with M. Ponsard's forno-convertisseur lined with one of the Blaenavon basic preparations. The maintenance of the necessary highly basic slag was effected by the addition of lime and a certain amount of ore, as prescribed by Mr. Thomas, the patentee of the process, who assisted at the operations. In the first cast of four tons, notwithstanding that the operations were conducted under very unfavorable circumstances, an analysis of the steel showed that 90% of the phosphorus contained in the pig had been removed. An examination of samples taken at intervals shows a progressive decrease of phosphorus in the bath and its transference to the slag; the amount of silica in the latter being kept at about 22%. A somewhat more basic slag is, however, generally preferred. The second cast gave very similar results. As the Ponsard apparatus is able to deal with pig very low in silicon there appears to be now no class of pig which may not be considered as available for the manufacture of steel. The only impurity which is not removed almost completely is sulphur, though this is eliminated to a considerable extent; fortunately, however, sulphur is readily removed in the blast furnace. We understand it is now in contemplation to regularly work the Ponsard converter in combination with the new basic process on the highly phosphoretic pig of Belgium and Germany. This will give an economy of from 30 to 50 francs a ton over the use of Bessemer pig, and give a fresh life to the drooping fortunes of the manufacturers of phosphoretic pig.—*Iron Age*.

SCIENTIFIC PROGRESS.

Progress of Electric Lighting.

Prof. Tyndall devoted one of his recent lectures before the Royal Institution of London to a brief review of the progress which is being made toward the practical introduction of the electric light. He commenced by saying that the electric light has been known for 70 years—as in 1808, and again in an improved form in 1810, it was shown to audiences at the Royal Institution. Sir H. Davy's carbon points "threw sunshine into the shade," and in 1808, 2,000 pairs of plates produced such heat from the current they gave that quartz and calcium were melted as wax. It was early known that to produce heat and light in a circuit there must be resistance. This was illustrated by a wire composed alternately of platinum, which resists, and of non-resisting silver, when on the passage of a current the platinum became dazzlingly white hot. A non-resisting copper wire will carry enough electricity to split a resisting oak tree. In the case of two carbon points this resistance causes the one point to waste with double the rapidity of the other. This is one of the two great obstacles to the general introduction of the electric light. The second is a more serious one, depending on an inexorable law of nature which demands an expenditure of force of one kind for the production of another.

Zinc may be burnt in air—that is, oxidized; it may be also "burnt" or oxidized in acidulated water; but it has to displace the oxygen from the hydrogen for this to occur, and four-fifths of the heat produced are used up in this process. So that when zinc is thus "burnt" only the remaining one-fifth is available. The rate of "burning" makes no difference; one ounce of zinc, for example, always gives out the same amount of heat. This "burning" of zinc, which had been used in the production of electricity, was an expensive fuel, and this seemed to be a very great drawback to the general use of the electric light.

In the year 1831 a discovery was made by Faraday—that of magneto-electricity. He showed that when the earth's lines of magnetic force are cut, an electric current is produced. Prof. Tyndall quoted Faraday's saying, that he would rather occupy himself in finding fresh effects than spend his time in exalting those effects. But it was the exaltation of those effects which he first studied in a simple way which has led to the present possibilities of our electric lighting.

In 1854, Werner Siemans, of Berlin, invented what is now known as a Siemans armature, in the working of which there is only the ordinary mechanical friction to be overcome. Working the machine by hand, the expenditure of muscular force becomes apparent as heat through the machine. But this and the Wylde and Gramme machines in the same way show that the external work falls short of the originating work.

Now, whatever electricity is, it is a swift carrier of heat. We have motive power converted into current, and then we can have current converted into motive power. For example, Sir William Armstrong has his electric light worked by a water wheel. The great advance on Faraday's spark of 1831, as to practical use, is the use of cheap fuel—coal—for obtaining through the steam engine the motive force required. All the various modifications of the light as now used depend on this. Prof. Tyndall gave a historical sketch of the various arrangements, beginning with that of Mr. Holmes in 1862. He said he did not believe that any fresh *scientific* discovery was needed to make the electric light of general application to large places. The scientific man knew what different natures of machines were required to do the different kinds of work to be done. It remained now for *mechanical skill* to carry out the work. In conclusion he pointed out the mistake of those who, like Cuvier, spoke with contempt of those whose practical skill carried to utility the experiments of the philosopher.

AFRICA AGAIN CROSSED.—A Portuguese explorer, named Pinto, has recently arrived at Transvaal in Southeastern Africa, having crossed the continent on an exploring expedition, traveling from west to east. The latitude of his course is not given, nor, as yet, any particulars in regard to his observations and discoveries. His route, however, must have been many degrees south of Stanley's route, and will, no doubt, add much to our rapidly increasing knowledge of the geography of Central Africa.

A New Light.

The English papers are largely discussing "a new light," which is now, however, only in the fact that it is an intensified gaslight. It is by some called "the albo-carbon light." This light consists in the use, as an auxiliary to common gas, of some properties of pure white carbon in the solid form of small cylinders; not much unlike in appearance to a stick of pure white candy.

The machinery required to adapt the feeder and enricher to an ordinary gas burner is extremely simple, and can easily be adjusted by anyone skillful enough to fill and trim an ordinary table lamp. Albo-carbon thus stands in favorable contrast with the elaborate machinery at present required for the production of the electric light. While it economizes the consumption and improves the quality of the gas, it involves no change in mains, meters or piping, or the general apparatus of gas service. In the case of single lights, the apparatus consists of a metallic chamber of spheroidal form, fixed at a slight distance from the burner. In this vessel the albo-carbon is placed, and the substance, becoming liquefied by heat, gives off an inodorous vapor, which mingles with the gas made to pass through the vessel, and produces a combination of illuminating power vastly superior to that of common gas. The enriching material is a form of naphthaline, and is clean, portable, and inexplosive.

The proprietors of the patent claim that albo-carbon causes no obstruction and leaves no residuum; and that the vessels in which it is placed may be replenished without the slightest fear of accumulating deposits, so perfectly exhaustive is the evaporation of the substance under heat. At a recent exhibition of the light near London, a variety of interesting photometric tests were applied to the light, and its power was gauged and measured under a variety of aspects, one of the most pleasant of which is its hue, which, while intensely brilliant, is cheerful and sunny, while the shadows cast by objects illumined by it are not of that dense darkness which contrasts so strongly with the moonlight brightness of the electric light. Gaslight, enriched by albo-carbon, is a warm, sustained, and steady light, not, however, calculated to fatigue the eye; but its value was made known most readily and most convincingly when the spectators passed from the brilliantly-lit eastern section to the main body of the building illumined by common gas, under which it presented an appearance of well-nigh murky dimness.

A NEW PHENOMENON IN STATICAL ELECTRICITY.—M. E. Duter, in a paper read before the French Academy in December, showed that when a Leyden jar is charged with either positive or negative electricity, its internal volume increases, and that this effect is a new phenomenon, unexplainable by either a theory of an increase of temperature or of an electrical pressure. The experiment was performed by means of a flask-shaped Leyden jar, with a long tube attached to its neck, and containing a liquid which served as the inner armature. The author's attention had been called to the fact that this phenomenon had been observed 10 years ago by M. Gori. His researches, just made public, leave no doubt of the accuracy of M. Duter's view, that the glass of the jar really expands. According to the theory of elasticity, the effect of an internal pressure in a hollow sphere is in the inverse ratio of its thickness. M. Duter, therefore, had three flasks made of the same volume, but of thicknesses of 4 mm., 0.8 mm., and 0.5 mm. respectively. They were filled with water and enveloped with tin foil. Each carried a capillary thermometer tube, in which the variations of the hight of liquid served to measure the changes in volume due to electrification. He found that these changes were imperceptible in the thick glass, very marked in the flask of mean thickness, and rose to 30 mm. in the thinnest. The variations in volume were very nearly in inverse ratio of the square roots of the thickness.—*Scientific American*.

A NEW PHONOGRAPH.—Mr. Johnson, Mr. Edison's chief assistant at his Menlo Park laboratory, has been for some time engaged in improving the telephone and the phonograph. He has accomplished what no other one has ever yet been able to do—in the recording by means of the phonograph of words transmitted by telephone with such success that they could be repeated by the speaking machine with sufficient distinctness to be understood. This was, of course, done by the employment of Edison's new electro-motor receiver, the only instrument yet devised that delivers sounds with sufficient power for the purpose. Mr. Johnson has also nearly completed the invention of a new phonograph which he claims will be adapted to the practical use of business correspondence, and the possibility of recording telephonic messages, as proved by yesterday's experiment, will greatly extend the uses of the phonograph for business purposes.

A TELEGRAPHIC WRITING MACHINE.—The London papers state that an entirely new telegraphic system of writing has been devised by Mr. E. A. Cowper, a civil engineer of that city. In writing, ordinary characters are used at the transmitting end of the line, and no receiving clerk is required in close attendance, or for the purpose of noting or translating the message. It is a real telegraphic writing machine. The writer in London moves his pen and simultaneously at Brighton another pen is moved as though by a phantom hand, in precisely similar curves and motions.

The Mining Share Market.

This week has been a continnation of the disasters, dullness, and misfortunes of the last. There has been little or no life at all in the market. Prices have perhaps not been as low as those attending former panics, but never has there been less movement and more sluggishness than now. Beyond a doubt the election for the adoption or rojection of the proposed Constitution is to some extent affecting values and business, and so far as this influence does extend it must be expected to remain until the excitement attendant on the election is over and the uneasiness dispelled. The opening of the week showed a slightly better tone than prevailed at the close of last, but this soon shaded off as to prices and amount of custom, to the sickly condition noted above.

For several days there was an almost entire absence of business as well as fluctuations. The last day or two there was a faint streugthening and a little more briskness in the movements. Ophir, Mexican, and Chollar have been the most active aud Bodie stocks generally have attracted some attention. It has been understood for some time that the insiders were intending to strengthen their position with the stockholders by economy manifested in the cutting down of official salaries and reduction in the number of superintendents and foremen in the mines connected by drifts and levels. Flood & Mackay are reported to favor strongly this policy, recognizing how great an economy is necessary in prospecting the Comstock during the present year.

A Chance to Visit Shasta and Other Northern Counties.

Those who think of visiting the great northern region of the State during the coming season and viewing its magnificent scenery and boundless resources, will be interested in the announcement that special arrangements have been made by the Central Pacific Railroad with the C. & O. C. L. Stage Company, whereby they will be able to place on sale during "the season," commencing May 1st, (next), at their office in this city and at Sacramento, "*Special Excursion Tickets*," contract limited to 30 days from date of sale, at the following rates for the round trip:

No. Miles fr'm Reading.	To Station named and Return.	From San Fran'co	From Sacramento.
22	U. S. Fishery—Allens	24.50	19.50
44	Slate Creek	28.80	23.80
54	Southerns	30.80	25.80
64	Lower Soda Springs	32.80	27.80
65	Castle Rock	33.00	28.00
99	Upper Soda Springs	33.80	28.80
77	Strawberry Valley—Sissons	35.40	30.40

The "U. S. Fishery" is on the Cloud river, at the only point where that stream is touched by the stage road, and is two miles below the hotel at "Allens" station. Slate Creek, Southern's Lower Soda Springs, Castle Rock and Upper Soda Spriogs are on the Sacramento river. "Strawberry Valley" (Sissons) is at the base of Monnt Shasta. At "Sissons," Upper and Lower Soda Springs, guides and horses are provided for excursions to the summit of Mt. Shasta and to the salmon and trout fishing stations and "deer licks" on the head waters of the Cloud river.

"To Leadville and Death."—Under the above rather startling heading the Cheyenne *Leader* comments upon the heavy tide of immigration that is setting towards a certain mining district in Colorado reputed to be rich in silver-bearing lead ores. In that immigration, stimulated into undue proportions by the most unwarrantable means, the *Leader* sees the portent of terrible disappointment, destitution and suffering; the town of Leadville, the central point of this attraction, being already overrun with multitudes of half famished, diseased and nearly desperate people. Being at a great elevation this locality, which remains deeply buried under the snow, is greatly liable to pneumonia and other diseases of the respiratory organs, from the effects of which hundreds have already died or are now suffering with little prospect of recovery. This journal charges that these unfortunate people have been induced to rush off to that inhospitable region in the dead of winter through the exaggerated accounts published about its mineral wealth by the agents of transportation companies and others interested in promoting a movement of this kind. If now a paper issued on the very highway to this fatal locality and likely to be benefited by such immigration, feels constrained to speak thus deprecatingly thereof, we may feel assured it has good reasons for entering its protest against both the movement itself and its active promoters. This action is significant of danger and ought to be accepted as a warning signal by those who, under the excitement caused by these extravagant accounts, may have it in contemplation to visit this deadly and greatly overrated locality.

We would call the attention of parties engaged in quicksilver mining, or other pursuits of like nature, to the advertisement, in another column, of the patent Life Saving Respirator.

Mining Summary.

The following is mostly condensed from journals published in the Interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Phœnix.—Plymouth Cor. *Ledger*, Mar. 29: The Phœnix company have been obliged to delay the working of the mine on account of the scarcity of timbers. It is expected that the mine will resume work in a few days. The timbers are jammed in the stream, and a large force of men are now at work to extricate them. The mill is running on rock accumulated on the dump. There is enough to last two or three days. A great many timbers are needed in the workings of this mine. The ground is heavy, and the ore body large, and the vast space caused by the excavation of ore has to be substantially timbered. The tunnel running south from the north shaft is making good progress. It has advanced between 400 and 500 ft, and is intended to strike the vast ore body of the south shaft at the depth of 1,200 ft.

Mining Notes.—There is a hitch in the claim south of the Phœnix. Work has been suspended for the present. The Phœnix company made application for a patent, but are barred by a prior claim, which must be purchased before their title can be passed upon by the United States. Thomas Bowden, amalgamator at the Phœnix, says that the new quartz claim owned by their company will pay $100 per ton. The claim is located on the east side of Indian creek, one mile north of Plymouth, on Jackson Gregg's land, and is said to be on the Phœnix lode.

Volcano Items.—The Confidence quartz claim has been started up. Four men are at work sinking, and the erection of hoisting works is talked of. A Santa Cruz company are going to sink a shaft for gravel half a mile east of the Confidence, on the same ridge. The great tunnel is in over 1,200 ft. It has only just got to work again after the robbery of the powder and burning of the magazine. A custom quartz mill is a desideratum in Volcano district. Stewart's mill is kept constantly running on Down's rock, with no prospect of being able to do anything for other parties. A 10-stamp mill for custom purposes would pay well, besides aiding materially in the development of the mineral resources of the district.

CALAVERAS.

Banner Mine.—*Chronicle*, Mar. 29: Active operations at the Banner mine, Mosquito, have had to be temporarily suspended in consequence of the disability of the boiler that runs the hoisting works. The boiler was in such condition that the water could not be kept from the mine, necessitating a suspension that will be but short. A crushing of rock from the Banner mine, 57 tons, has lately been made in Garland's mill. The yield was not quite up to the average.

Jottings.—Operations have been resumed at the well-known Anderson Flat mine, West Point district, under the supervision of Desmond, agent of a San Francisco company. The pumps were started up this week, and as soon as the shaft is freed of water, stoping will be commenced. Extremely rich rock is being obtained from the Charlotte mine, at Mosquito, Messrs. Peck & Potter proprietors. The ledge is a very promising one, but not yet sufficiently developed to determine its permanence and value.

EL DORADO.

Pilot Hill.—Placerville *Democrat*, Mar. 29: Quite a strike has been made in the Victoria mine, Hogg's Diggings. The ledge is seven ft thick and the ore from the recently-opened pay chute prospects at the rate of $75 per ton by mill process. The claims of Stephenson and Mendez afford prospects scarcely less flattering than the above. The Bowlder gravel mine is run night and day, under the superintendence of Prof. Wheeler. No doubts are entertained but that a big clean-up will be the result of this winter's work. Adjoining the Bowlder claim ex-Justice M. L. Warner is vigorously at work on his gravel bank.

INYO.

This Modock.—*Independent*, Mar. 29: By far the most important mining work now going on in Inyo county is the deep tunnel enterprise of the Modock Con., at Lookout. It will develop our most prominent base metal mine at the greatest depth yet attained, the level being 1,000 ft below the ledge croppings and 100 ft deeper than the new Union shaft at Cerro Oordo. The face of the tuunel is now in beyond the vertical line of the old bodies of lead ore, but the strong pitch into the hill of the accompanying silver belts—the Confidence ledges—renders it difficult to judge how much further the tunnel must be driven to intersect the ledge. It must, however, be in close proximity to it now, and a strike is almost daily expected.

Snow's Canyon.—The mill is in operation on custom ore, and a new impulse thereby given to working and prospecting the numerous small, rich gold ledges of the district.

New Coso.—There is a much better feeling in and about the old mines of Darwin since the New Coso furnace, by its great reduction of charges for smelting and liberal and prompt payment for ores on delivery, has practically carried out a plan whereby all the mines contribute ore to keep one furnace in constaut work. The Custer mine is in line on this matter, the old Defiance and others will soon fall in, while the Lucky Jim itself looks extremely promising for a good output of ore and bullion during the season.

MONO.

This Defiance.—*Standard*, Mar. 29: The shaft is slightly inclined, following the ledge, which dips to the east. The depth reached is 143 ft, from which point a drift extends north 168 ft. At the bottom of the shaft the lode is 18 ft in width; at a point 72 ft north in the drift it narrows to eight ft, while at the extreme face of drift north it again widens, and is 11 ft wide. The west, or foot wall, is as smooth and well defined as a ceiling; the eastern side of the fissure is somewhat broken. The filling between is largely composed of good looking quartz; but it is also subject to those whitish clay slips characteristic of the Silver Hill formation, so far as present depths have determined. There is an unusual amount of the black manganese coloring scattered throughout. In places the vein matter prospects high, while the average assay of the solid quartz is indicative of a good "milling proposition." The company have decided to put on steam hoisting works at once and follow the lode. The shaft will be enlarged to double its present size. The prospect would appear to justify a new vertical shaft, but the incline has been decided upon. A new ledge has been discovered a few feet west of the main one, surface prospects from which are very encouraging; gold being readily borned from the very croppings. This lode is almost three ft in width, and its discovery a result of accident.

The Standard.—The Burgess or Cook ledge has been developed north of the crosscut about 100 ft. At this point the ledge dipped sharply west, theu for a distance of 30 to 40 ft twisted out of the line of drift and was lost sight of entirely. In this short distance it seems to have turned a complete somersault, landing on its feet right side up and richer than ever, but pitching to the eastward at an angle greater than it had inclined in the other direction. The ore of this irregular vein is at present a "sight for sore eyes." Its rich ore is as full of the precious metal as the best of the Bruce, which ledge, by the way, is holding its own northward over 300 ft from the Bodie line. The Oildea is the prettiest ledge in the whole series; in fact, there is none in the whole district so clean cut as to walls and filling of bright, live quartz.

NEVADA.

Round Mountain Mine.—*Herald*, Mar. 29: The main tunnel is in 400 ft. It is large and commodious, being six ft in the clear, and is substantially timbered. They were obliged to run in a distance of 300 ft before the gravel was reached. There are two drifts brauching off from the main tunnel, and each of these is in a distance of about 200 ft. The gravel is very rich. There were a vast number of little particles of gold varying in size from that of a pin-head down to specks too small for the naked eye. There are about a dozen men at work in and about the mine, and they are taking out about 80 carloads per day. The gravel is easily mined, and as it is run out of the tunnel in cars, it is not very expensive getting it out. There are over a thousand carloads on the dump now, which will soon be washed.

Blue Tent Mines.—The mines have been kept constantly running since water was first gotten through the ditches. It has required good management to keep the water running all the time, owing to the many little slides which have occurred, but it has been done. The snow-sheds constructed over the ditches in the heavy snow belt have been an immense saving from breaks, as the snow coming down the mountain sides strikes the top of the shed and shoots over instead of hitting the flume or ditch, as it would otherwise do. These sheds will be extended as soon as convenient, so as to cover all places exposed to snow slides.

Moore's Flat Items.—The Blue Banks claim are about ready to begin washing. The Boston mine is running full blast. There are at present about 30 men employed in the mine, and more are engaged. They are paying $3 per day. The Miners' Union succeeded in convincing the managers of that mine that it would be better to continue the rate of wages at $3 per day than to attempt to enforce the proposed reduction. There will be a blast of 200 kegs of powder exploded under the bank of the Boston claim in a few days. The claims owned by the Chinese are running in full headway.

SAN LUIS OBISPO.

Placer Mines.—*South Coast*, Mar. 26: About 150 miners, principally Spanish people, are engaged in taking out gold, the average pay is probably $1 per diem. The mines are what are known as gulch diggings. The mines developed and now working are located in and on a number of dry guiches, all within a radius of perhaps two miles. The want of water is the great impediment in the way of more successful mining. Mr. Jackson and Thomas Fuller have located and proceeded to prospect in a systematic manner a piece of ground in the same gold belt, but four miles away from the principal mines, on a large stream which has a fine running stream of water.

SHASTA.

Igo Items.—Cor. Reading *Independent*, Mar. 27: Mr. R. Harvey has tried the strength of several tons of powder in the Hard Scrabble mines, loosening thousands of tons of gravel; the giants have since been throwing water with great force on this loosened mass, night and day, with good effect, while in other parts of the extensive mine blasting is going on, driving the bedrock cuts up to other high banks, to give work for other giants. Dunham & Co. have commenced a ditch, taking the water out of Cottonwood near Mr. Taylor's, below Eagle creek, running it down to the mouth of Hulan creek, where there is good diggings. There is a large force now working on the ditch, and it will soon be completed. Messrs. Prevost & Co. are still driving their tunnel ahead on one of Mr. Engle's mines, with good prospects, as also are Messrs. Wilson & Co. Work in the mines of the South Fork district is going ahead as well as it can, considering the weather. Wright & Co.'s arastra has been delayed by the rain, but with one day more of good weather, it will be completed; they have already commenced hauling quartz; and are in good spirits.

Big Thing.—A rich ledge has been discovered near Slick Rock, about three and a half miles from the Conway location, which from all accounts beats anything yet discovered. The ledge is owned by William Murray, E. G. Parker, Fred. Ten Eyck and Mr. Vaudeveer. Mr. Murray says that he has drawn a line over the ledge to a distance of 1,000 ft, and that it will average three ft in width, the rock in some places assaying as high as $1,000 to the ton. It is composed of rotten quartz that is completely speckled with gold.

TUOLUMNE.

In Operation.—*Independent*, Mar. 29: The new 10-stamp mill of the Gold Hunter Consolidated mining company started up March 21st. The claim of this company is six miles east of Summerville, on Big canyon, and 16 miles east of Sonora. Their vein is on the same range of slate on which is situated the Ferguson mine and the celebrated Hight mine, in Mariposa county. The mine has been six years in process of development. The shaft is now down nearly 200 ft, and shows good rock in the bottom, the vein running from 18 inches to four ft. Some of the rock prospects big, having an abundance of free water, and the rock being easy of extraction, they can get out and mill the ore at a very low figure. Three hundred tons of rock are now on the dump, the levels are all run for stoping, and ore enough is in sight ready to break down to keep the mill employed a year. The mill was built by D. Seeber, and contains all the modern improvements. The battery is driven by a 30-ft iron wheel. The machinery has run right along like a clock without change or stoppage.

Mining Items.—At the Keltz mine, above Columbia, the shaft is now going down in good rock—more than paying the expense of sinking. The shaft is now down 100 ft, and after getting 80 ft deeper a second level will be run. The mill is doing good work on rock from the first level. The bottom of the shaft shows a vein three ft wide. Wm. Sharwood, T. C. Birney and M. Moyle are the owners of the mine. The Omega tunnel is being re-opened and run into Table mountain from the Jamestown side, by John Oliver and the Daley Bros. Murry & Kyser have struck rich quartz on the Black Hawk hill, near Brazee's saw mill road at the head of Bald mountain. Geo. Morgan, Columbia, has "struck it big" on the old St. Louis claim, between Spring gulch and Rose gulch, near the Shangbai claim.

NEVADA.

WASHOE DISTRICT.

Dardanelles.—Gold Hill *News*, Apr. 3: Active operations have been resumed at this mine. The new shaft, which is 100 ft deep, is being sunk as expeditiously as possible. The situation of the new shaft has been well chosen. There is ample dumping ground for years to come; the railroad track runs within 100 ft, facilitating the delivery of wood and timber, and it is closer to the ledge than the old works.

Con. Virginia.—The repairs to the shaft have not yet been completed. The main drift to the C. & C. shaft on the 1500 level is still receiving attention in the line of enlargement and re-timbering, as also is the joint drift on the 1650 to the shaft. The joint west drift, 2150 level, continues in favorable-looking vein material, carrying stringers of quartz, through which it is making three ft per day. It is now in 326 ft. The C. & C. shaft is 185 ft below the 2150 level.

Utah.—The V-bob has been delivered and is being set up on the surface, and the braces, etc., adjusted. The drilling for the anchor bolts is finished. The main incline is down to-day 363 ft on the slope, below the 1350 level.

Alta.—The three-compartment incline, joint with the Benton, is down and timbered 210 ft on the slope, below the 1550 level. It follows the pitch of the ledge.

Julia Con.—The pumps above the 1600 level have all been disconnected except two, the upper clacks of which have been taken out, causing them to answer the purpose of balance bobs. All the water pumped is now discharged into the Sutro Tunnel, and the 2000 level will soon be reached.

California.—The joint Consolidated winze from the 1950 level is down 105 ft. Both are in hard blasting rock. The joint west drift, 2150 level, is in 326 ft, and penetrating a fine vein formation, carrying stringers of quartz. The C. & C. shaft is being sunk at the rate of two ft per day, and is 185 ft below the 2150 level. The flow of water continues unabated.

Sierra Nevada.—Sinking in the incline has been resumed. The water is increasing slightly, but the flow is readily handled. The drift on the 2200 level is being graded and timbered very rapidly. The ventilation of the mine is excellent, a strong current of fresh air coming in from the main shaft and through the connection with the Utah.

North Bonanza and Flowery.—The boilers are in place. The joint shaft is making three ft per day, and is 66 ft below the second station. The north lateral drift from the first station being rapidly pushed along the ledge, shows a regular wall of clay several feet in thickness.

Justice.—The surface workings in the Waller Defeat grounds are still yielding their usual amount of ore. The donkey engine greatly facilitates operations and lessens the cost of extracting the ore. The yield is 35 tons per day.

Gould & Curry.—The joint east drift, 1700 level, is making six ft per day through good working ground, its face 712 ft from the lateral drift. The Curry winze from the 1700 to the 1900 level is being retimbered. In the Osbiston shaft a bob-pit is being cut out. The drain tunnel is making very rapid progress toward the shaft, the ground being soft and favorable.

Union Con.—The 1450 drift north, connecting with the Sierra Nevada, is still being repaired. The joint Mexican incline winze from the 1600 level is down 320 ft, and is being met by an upraise from the 2000 level.

North Con. Virginia.—A set of timbers per day is being put in as the shaft follows down the upraise from the 1700 level of the Sierra Nevada. Ventilation in the shaft is continually improving. The superintendency of the mine has been placed under the care of Wm. H. Patton, the well-known bonanza superintendent.

Mexican.—The joint Union incline winze from the 1600 level is now down 320 ft, on the slope, in favorable looking vein porphyry. The joint Ophir upraise from the 2100 level is penetrating hard blasting porphyry, its face 61 ft above the drift.

Best & Belcher.—The east drift, 1700 level, is nearing the perpendicular of the Osbiston shaft at the rate of six ft per day. Crosscut No. 1, 1900 level, is making about equal progress through good vein material carrying stringers of quartz. At the Osbiston shaft a bob-pit is being excavated.

Bullion.—The face continues in soft vein porphyry with streaks of quartz. The pipe for the new compressor has been laid to the 2150 level and the foundation completed.

Trojan.—The northeast drift from the third station is making three and one-half ft per day, through a promising vein formation consisting of quartz and porphyry. From the incline upraise above the second level, a drift is being run south through fine-looking quartz.

Yellow Jacket.—The new shaft is being sunk in very hard, dry ground. The drift on the 2400 level, and from the north winze, is approaching the shaft at the rate of six ft per day. The new air compressor is working well.

Overman.—The O & C shaft is down 550 ft. A pocket of water has been encountered which has stopped the work till the flow subsides somewhat. Some 60,000 gallons are raised per day.

Leviathan.—Work is being actively prosecuted in the lateral drifts both north and south on the 750 level, each making good advancement. The machinery and new cables are operating finely.

Exchequer.—The delay caused by the breaking of the pumping machinery of the Imperial has prevented the usual progress in the north drift, 2400 level, but the work has been resumed, the face of the drift being still in a fine formation of vein matter.

Mt. Hood & Vancouver.—The guides are not all yet in the shaft. The work has been delayed by repairs to the shaft, which had to be retimbered for a distance of 60 ft at the 600 level.

Caledonia.—The east drift, 1600 level, has been discontinued. The winze below this level is still in a mixture of clay, porphyry, and quartz, carrying considerable water. The O & C shaft is down 550 ft.

Hale & Noacross.—Timbering and securing the lightning drift. The pumps hold the water below the 2000 level while this work is being done.

Savage.—Pumping and holding the water below the 2000 level and retimbering the incline. Forty ft of this work have been completed.

Con. Imperial.—Work is now going on as usual and the drift is following the vein and intersecting some fine-looking feeders. The south drift, same level, is being pushed as rapidly as possible to connect with the 2400 level of the Yellow Jacket for needed ventilation.

Sutro Tunnel.—All the surveys have been made for the contemplated sub-drain and the grade is established. The preliminary work necessary to the commencement of operations has been completed, and the advent of Mr. Sutro is awaited to begin digging the drain.

Ophir.—The main incline is down 155 ft, on the slope, below the 2200 level, penetrating vein porphyry, carrying streaks of quartz. The joint Mexican upraise from the 2100 level is up 61 ft, and passing through hard, blasting porphyry.

Andes.—The main drift north on the 350 level is penetrating quartz of a favorable character. A crossdrift from a point 25 ft from the face has been started west, and is encountering small streaks of quartz.

Ward.—The work of bailing the water from the shaft is still going on, some 40 ft still remaining before the bottom, 1,400 ft, is reached. The water pipes have been laid from the tank to within 40 ft of the building. A roof has been put over the tank and it has been lined on the outside and a door put in.

Belcher.—The main incline is now 21 ft below the 2600 level, and guides have been extended to the bottom. On the 2300 level, near the south line, a crosscut has been started, which is now opening up a fine vein formation.

Silver Hill.—The east crosscut on the 1100 level is still showing up low-grade ore, and has its face 520 ft from the incline. A drift has been started south from the Justice workings in the Waller Defeat ground.

EUREKA DISTRICT.

Williamsburg.—*Mining Report*, Mar. 29: The main shaft has been sunk to a depth of 100 ft and a drift started on the vein; the latter being in about 50 ft. A winze has been sunk 40 ft on the ore body, and at the bottom the ledge is over five ft wide and assays about $300 per ton. The formation is a white clay with brown streaks running through it. Bunches of ore have been struck in other parts of the mine which assayed over $1,000 per ton silver. In another place a shaft was recently started, now down 10 ft, in which a well-defined ledge was struck. More work has been done than was really necessary, the mine not having been opened up in the proper shape, but if the main shaft be driven down to the depth of 200 ft, a level opened and a drift started for the ledge, it could be worked to a better advantage.

Kit Carson.—A contract, on which work was commenced a few days since, has been let to sink the shaft 100 ft further down. The large cavity mentioned some time since was followed down for a distance of 60 ft, when hard ground was struck. This formation lasted for a few feet and another cave was found. The immense amount of foul air which arose from this cave to the upper one, compelled the miners to quit work for a while as they were all getting sick. The object of the contract above mentioned is to sink the shaft to a sufficient depth to drift from the bottom and run under this cave, thereby furnishing a current of fresh air. The drift will be about 50 ft long. The first cave is 160 ft deep and almost perpendicular and the last one, as near as can be judged, is about 80 ft. There is crystal formation between the two. Considerable galena ore was found in the large cave.

REESE RIVER DISTRICT.

The Manhattan.—*Reveille*, Mar. 29: The 517 stope shows no falling off in either grade or size of ledge. The 517 west drift is being driven into the ore body as fast as possible. There is no change in the 560 stope, the ledge continuing small but rich. In sinking a winze from the 600 east drift a considerable body of very fine ore has been developed, which will soon be ready to be worked through the 675 level. The 825 stope contains a very large ledge, but the ore is not as high a grade as formerly, though still over $200 per ton. The winze in the 600 west drift of the North Star shaft is now down 40 ft. It will be continued down to a depth of 50 ft, when a drift will be run to prospect the ledge.

Western Nye.—Orantsville *Sun*, Mar. 26: Everything about the Alexander mine is looking well. The yield of ore continues unchanged. The north crosscut from the

[Continued on page 220.]

The Genesis of Cinnabar Deposits.—No. 1,

[A paper read before the Geological Section of the California Academy of Sciences, by S. B. Christy, Ph. B.]

There is no branch of theoretic geology which has greater interest both to the student and to the miner than the study of the nature and origin of mineral veins. It is the province of the geologist to make a careful study of the phenomena as they exist in nature, while on the other hand, it is that of the chemist to take up the study at this point, and, given the facts, to find an explanation for them.

The whole subject is one of the most difficult that chemistry and geology have undertaken, and even with the aid of all the appliances which modern science brings to bear upon its problems there is still much to be accomplished. Even to the general reader the names of Hall and Phillips of England; Daubree, Durocher, St. Clair Deville and De Senarmont of France; Rose, Bischoff, Pfaff and Fuchs of Germany; Hunt, LeConte, Dana and others of America, are too well known and appreciated to need any eulogy. But as only the special student is familiar with the progress which has been made in this direction, it may not be out of place to recapitulate briefly, what has been accomplished.

Fuchs in his interesting and valuable monograph *Die kuenstlich dargestellten Mineralien* has carefully compiled what has been done by the chemists and geologists already mentioned, as well as by many others. This record shows that nearly all the important native metals, their oxides, hydrates, carbonates, sulphates, sulpharsenates, sulphantimonates, sulphates and many of the silicates have been successfully reproduced. Among this list may be mentioned as examples, galena, argentite, realger, iron-pyrites, copper pyrites, mispickel, molybdenite, fahlore, fluor spar, quartz, corundum, opal, calc spar, aragonite, dolomite, witherite, strontianite, malachite, etc. These artificial minerals it is true were many of them almost microscopic in size, but they were proved to have the same physical properties, crystalline form, hardness, color, specific gravity, etc., as the native minerals, as well as the same chemical composition.

The methods by which they were produced have in common the condition of freedom of motion among the molecules which favors crystallization, but otherwise they vary widely. The following is a condensation of the list as given by Fuchs *(Die kuenstlich dargestellten Mineralien, p. 6.):*

1. Molecular rearrangement.
2. Sublimation.
3. Decomposition of vapors at a high temperatures.
4. Action of gases and vapors upon strongly heated solid bodies.
5. Melting.
6. Solution in liquids.
7. Slow union of dilute solutions.
8. Electrolysis.
9. Diffusion of solutions.
10. Union of substances which slowly act upon each other.

Of these ten methods, with perhaps the exception of No. 9, all have been observed in nature.

While it has been proved that some of these minerals may be produced by more than one method, as iron pyrites, quartz and cinnabar, others as the carbonates have been as yet produced in only one, it follows that the conditions which occur in any particular locality must be very carefully studied before we can decide in the matter. The results of the more recent observations and experiments, tend to show with increasing certainty the importance as a transforming agent of the solution of the alkalins carbonates and sulphides, especially when these act under the conditions of great heat and pressure. A constantly increasing number of phenomena are being explained by their influences, and the importance which was formerly attached to the sublimation theories is gradually decreasing.

The ores of mercury, however, partly from the fact that they have been but little studied, and partly from their easy volatility, together with the difficulty of accounting for their solution in any known reagents which are supposable in nature, has led to their being generally regarded as formed by sublimation. Even in so recent a work as that of M. H. Kuss, (*Memoire sur les Mines et Usines d'Almaden*, p. 47, reprint from *Annales des Mines,*) the author says: "We should always recognize in cinnabar the character of a vein substance carried to the surface very probably in the state of vapor."

The purpose of the present paper, is then, a discussion of the two theories as to the formation of cinnabar deposits. We shall endeavor to find an answer to the question, "Are cinnabar deposits produced by sublimation, or are they deposited from solution?"

In considering this question it will be necessary to review, briefly, the facts to be explained and the present state of knowledge with regard to the chemistry of certain of the compounds of mercury. The subject will therefore be divided as follows:

First—The facts to be explained. A brief synopsis of the nature of some of the more important cinnabar deposits.

Second—Some of the more important properties of cinnabar.

Third—The results of some original investigations on this subject.

Fourth, and lastly—A comparison of the relative probabilities of the two theories.

First—The Characteristics of Some of the Principal Cinnabar Deposits.

I begin with the one with which I am personally acquainted, that of New Almaden. This has already been well described by Prof. Silliman in the *American Journal of Science*, but a statement of its principal points may not be out of place. This mine is situated about 13 miles southwest of San Jose, in a low range of hills. This range begins at the Hacienda creek and runs parallel to the Coast range for about four miles, when it is cut by the Guadalupe creek. These hills, so far as exploited, are composed of serpentine overlaid by a layer of magnesian schists, which are nearly always black, and which on analysis I have found to contain much iron and some alumina. Overlying these are other schists which become more and more aluminous until generally they change into clay slates. These latter rocks are everywhere greatly metamorphosed, in some cases so much so that they approach in appearance the darker varieties of jasper. These overlying schists have the same general dip as the surface of the hills, modified, of course, more or less, by subsequent erosion.

The serpentine gave as the result of qualitative analysis large amounts of magnesia and silica, with smaller amounts of iron and alumina, and traces of chromium, manganese, calcium and nickel.

Lying between these magnesian schists (to which the Mexican miners have given the name "alta," and the Cornishmen "banging wall") and the serpentine beneath is found the deposit of cinnabar. The "vein matter" itself appears to be a serpentine somewhat altered by infiltrated waters. It is sometimes extremely tough as well as hard, and is difficult to mine; at other times it is very soft and fragile. A qualitative analysis of a specimen of the former variety, selected by mining Capt. Gray as the hardest rock in the mine, proved it to be essentially hydrated silicate of magnesia, with small amounts of iron, chromium, manganese, calcium and nickel.

Associated with the cinnabar are found dolomitic crystals of pearl spar, iron pyrites, chlorite, and, extremely seldom, crystals of quartz. Another notable fact is the occurrence of a bituminous substance resembling idrialite. This substance is wrongly stated by M. Kuss in the memoir above cited to be a "veritable coal." It is not a true coal. It sometimes has the appearance of a soft bituminous coal, but when heated melts and flows like bitumen. Ordinarily it is found in the liquid condition, and flows from the drusal cavities in which it is contained when they are opened. When strongly heated it gives off highly inflammable hydrocarbon vapors, and leaves an intumescent coke, which is very light and fragile and burns with scarcely any ash. Sometimes the schists spoken of are impregnated with a hydrocarbon more like petroleum, as in the 1500-ft and 1600-ft levels of the Randolph shaft.

In the part of the mine near the Cora Blanca shaft is a sheet of dolomitic limestone which runs from the top to the bottom of the mine. This lies immediately beneath the alta in most cases, although some ore has been found above it. It varies in thickness from one to two feet. In analyzing this, among the matters insoluble in hydrochloric acid there were found some microscopic crystals of iron pyrites. In the various workings there seem to be layers of sandstone, particularly in the Cora Blanca, They seem always to overlie the vein matter, though in the latter mine they are impregnated with cinnabar. The exact position and significance of these latter rocks I have been as yet unable to determine. It is probable, however, that these sandstones are more or less local in their origin, being the result of slightly varying physical conditions which existed during their deposition.

Native mercury occurs rarely, chiefly in the sandstone of the Cora Blanca (also on the 1500 and 1600-ft levels of the Randol shaft, where it ran out of the shattered alta upon opening out the vein matter where it was very much broken up by faulting.)

In many cases the micro crystals of cinnabar are most intimately mixed with those of dolomite, and occasionally with those of quartz. The cinnabar is nearly always so thoroughly impregnated with bitumen as to leave a carbonaceous residue on distillation.

Throughout this interesting mine there are many evidences that chemical and mechanical action has taken place. A strongly alkaline spring with free carbonic acid (the New Almaden Vichy spring) is still active at the Hacienda. Occasionally springs with sulphydric as well as carbonic acid are opened by the drifts. In the mine itself "slickensides" (surfaces polished as smooth as glass by slipping on each other) are frequently meet with, and often large masses of serpentine are broken off bodily and are buried in the superincumbent mass of alta.

The ore is very irregularly distributed throughout the vein matter, frequently disappears altogether, and reappears in such an uncertain way, that despite the well established course of the ore body or "vein" itself, there is a great deal of skill required to properly exploit the mine.

The Guadalupe and the now abandoned Enriquita mines appear to belong to the same formation, but it would require a thorough examination of all of this series of mines to trace out this and other interesting questions.

I have dwelt thus long upon some of the geological characteristics of this mine, because it is, in many respects, typical.*

Von Cotta, in his *Erz Lager Staette*, Vol. II., p. 616, gives the following as the characteristics of the principal cinnabar mines of Rhenish Bavaria, Bohemia, Alps, upper Italy and Spain.

Country Rocks—Sandstone, clay schists, trachyts, talcose mica slate, limestone and quartzose mica slate.

Ore Matter—Cinnabar, blende, galena, fahlore, limonite, amalgam, copper pyrites, iron pyrites, silver ores, native quicksilver, horn quicksilver, idrialite, lehererz, magnetic iron pyrites.

Vein Filling—Quartz, hornstone, heavy spar, calc spar, dolomite, spathic iron, gypsum.†

Such a general distribution of carbonates certainly argues against the sublimation hypothesis. With a few exceptions, these cinnabar formations are not in immediate relation to igneous rocks, but rather to metamorphic rocks: In some cases (seven out of sixteen), the deposits are described as veins, the others as in clefts (*klufte*), layers, or impregnations. Usually, with the notable exception of Almaden in Spain, cinnabar does not seem to form in true fissure veins, but rather to be interspersed in the ore body in a very irregular manner, as is indicated by the term impregnation.

Second—The Chemical Properties of Some of the Salts of Mercury.

The inquiry here becomes limited within very narrow boundaries. The soluble salts of mercury, which could exist in any natural mineral waters, are very few. The mercuric chloride is, at first sight, the most probable one, the sulphate not existing in solution except in the presence of a free acid. Still, salts of mercury have been proved to exist in at least one mineral water. In the analysis of the water of the spring "du Rocher" (*St. Nectaire-le-haut, Puy-de-Dome*, by M. Garrigon, *Comptes Rendus*, XXXIV., p. 936), there is given as a constituent of the water, a small amount of mercury. It was very small; the total amount of all the heavy metals, including mercury, estimated together was only 0.008 grammes per liter. But the author states that he obtained enough mercury from 500 liters to exhibit it in the metallic state.

It seems much more probable, however, that the salt of mercury usually regarded as the most insoluble is the one in which we are directly interested, *i. e.*, the mercuric sulphide. This salt, as is well known to all chemists, while insoluble in almost everything else, in both of its modifications, the black, or amorphous, and the red, or crystalline, is soluble in solutions of the alkaline sulphides, containing free alkali. This fact is recognized both by Rose and Fresenius, but I have been unable to find any exact statements as to its solubility. Prof. V. Stein, in *Dingler's Polytechnisches Journal* (*Bd.* 138, *S.* 390,) states: "I find that sulphydrate of sodium, as well as potassium, dissolves cinnabar, even in the cold, with the same ease as water dissolves sugar." This statement is, to say the least, a great exaggeration. He also states that the polysulphides of the alkalis failed to dissolve any noticeable trace of the sulphide of mercury. The most careful work upon the subject is, perhaps, that of Dr. R. Weber, *Poggendorf's Annalen der Physik und Chemie* (*Bd.* 97, *S.* 76). He finds that sulphide of potash dissolves the sulphide of mercury only in the presence of free potash or soda. He states that the addition of carbonic acid, sulphydric acid, or flowers of sulphur precipitates the mercury from such a solution completely. On the other hand, it is well known that solutions of the alkalins polysulphides slowly change amorphous mercuric sulphide to the crystalline variety. This would hardly be the case unless partial solution had taken place. It is also a well-known fact that the mercuric sulphide, when it is suddenly precipitated from alkaline sulphide solutions, either by excessive dilution or saturation with carbonic or other acids, is not in the form of crystalline cinnabar, but in that of the black amorphous variety. And, finally, we have the well-known fact that the amorphous sulphide volatilizes (out of contact with the air, below a red heat, 500° C., unchanged,) and is deposited as crystals of cinnabar in cooling. On the other hand, if the vapor is rapidly cooled, the deposit is the amorphous black variety.

Such, in brief, is the not altogether satisfactory state of knowledge upon this subject.

*For a description of the principal cinnabar deposits of California, see *Les Gisements de Mercure de Californie*, par M. G. Rolland, *Annales des Mines*, 1873.

†For a full description of the deposit of Almaden in Spain, see the article of M. Kuss above cited, p. 10–49, or the translation by the writer, p. 6, etc.

[Concluded Next Week.]

A new use for sawdust is reported in the *Polytechnic Review*. It says that a French authority recommends the use of sawdust instead of hair in the mortar to prevent its peeling off. His own house, exposed to prolong storms on the sea coast, had patches of mortar to be renewed every spring, and after trying without effect a number of substitutes, he found sawdust perfectly satisfactory. It was thoroughly dried and sifted through an ordinary grain sieve to remove the larger particles. The mortar was made by mixing one part cement, two lime, two sawdust, and five sharp sand, the sawdust being first well mixed dry with the cement and sand.

"A half-ounce letter taken to the sun," says Proctor, "would weigh four and a half tons, if the attraction of gravitation remained the same as on the earth in proportion to the mass."

The Engineer.

Marine-Engine Economy.

One of the most suggestive illustrations that can be adduced as showing the advances made within the last 40 years in marine-engine economy is derivable from an examination of data of recorded averages of Atlantic steamships; and more especially of those of the Cunard paddle-wheel steamer *Brittannia*, in 1840, and the White Star screw-steamer *Brittannic* in 1877. Of the first vessel the average duration of passage was 14 days and 8 hours, and the consumption of fuel, 544 tons, the daily consumption thus being 38 tons. Assuming the average cargo at 225 tons, this gives 48.35 cwt. of coal per ton of cargo; and the averags speed in knots per hour being 8.3, the consumption per knot was 3.8 cwt. The indicated horse-power was 740, and this consumption per horse-power, 4.7 cwt. The *Brittannia* displaced but 2,050 tons, and this must be taken into account in comparing her with the *Brittannic*, whose displacement is more than four times as great, or 8,500 tons. That vessel, in 1877, showed an average passage of 7 days, 10 hours and 53 minutes, an average daily consumption of fuel of 100 tons, or total consumption of 745 tons. Her cargo is 3,350 tons; consumption of fuel per ton of cargo, 4.45 cwt; average speed, 15.6 knots; consumption per knot, 5.3 cwt.; indicated horse-power, 4,920; consumption per horse-power, 1.9 cwt. In other words, we are now enabled to transport 15 times as much freight across the ocean in one-half the time at an expenditure of less than one and a half times as much coal as in 1840.—*The Engineer.*

The Telegraph and Railroad in Japan.—The government of Japan seems to be particularly distinguishing itself in the extension of its telegraph system. There are now no less than 125 telegraph stations and 5,000 miles of wire in operation; 1,000 miles more in course of construction, and still further extensions are contemplated. The telegraph insulators made in a village called Imari in the province of Hizen are of such an excellent quality that orders for them have been sent from Europe. It is the first aim of the government to provide good highways in all parts of the empire before entering upon any general system of railroad building; but on the 26th of July, 1876, a line of railroad 48 miles in length was completed between Hiogo and Kioto, and now a line has been commenced between the latter place and Ostu, and is expected to be completed in three years at a cost of about $1,000,000. The railroad between Hiogo and Kioto is constructed of the best imported material and passes through ons of the richest and most beautiful agricultural districts in Japan. Seven trains leave and arrive at Hiogo daily, and the passenger and freight traffic are constantly increasing. The iron bridges of this road, one of which is 1,300 feet in length, are a credit to the government and contractors.

Resistance of Ships Due to Their Depth—Information Wanted.—Every ship is probably accompanied by waves whose natural speed depends on the vertical depth to which she disturbs the water; and consequently where the speed of the ship exceeds that natural speed, there is probably an additional term of resistance depending on such excess. In a paper before the British Association, Prof. Rankine gives some observations that prove the existence of waves whose speed of advance depends on the depth to which the vessel disturbs the water. The relation between those waves and the resistance, remains a subject for future investigation; but to facilitate that investigation, he calls for farther observations, such as the measurement of the angles of divergence of the wave ridges raised by various vessels at different speeds, and the determination of the figures of those ridges—also the mean depth of immersion as found by dividing the volume of displacement by the area of the plane of flotation, and that not only for the whole ship, but for her fore and after bodies separately.

A very useful invention has been devised by a Mr. J. N. Holmes. It consists of a bomb which can be fired at a distance of miles from the coast or from a ship, and it is so contrived that it will float upon the surface of the water and emit a very powerful light for about an hour. By its use in war the approach of a hostile fleet during the night might be disclosed, and in time of peace it could be employed with advantage in rescuing crews of vessels stranded in the darkness, or in occasionally warning ships approaching too near a dangerous and low-lying coast.—*Nevada State Journal.*

One-Idea Men.—An exchange remarks that they are seldom healthy, wealthy or wise—nature loves variety; to which another answers: No one is able to do all things. Concentration of thought and effort in one direction are necessary to distinguished success. Watt was not a jack at all trades if he did invent the steam engine.

Engineers of steamships have found that the best lubricants are glycerine for the cylinders, and castor oil for the bearings. When castor oil is used, the main hearings are seldom heated. Only the best glycerine can be employed with advantage, but when it is of a high grade the results leave little to be desired.

MODELS FOR TENEMENT HOUSES.—The Plumber and Sanitary Engineer of New York, conjointly with four other gentlemen, some time ago offered a premium of $500 for the four best models of a tenement house, to be erected on a lot 25x100 feet, enclosed by buildings at the sides and in the rear, the walls to be of brick and the floors of timber. One hundred and eighty designs had been received at the Leavitt Art rooms. A prime object is to secure a proper distribution of light and air for poor occupants, at such rates of rental as shall be moderate, and yet secure a profit on the investments. These designs come from the architects of 30 cities. The time for a decision between the competitors has not yet been announced.

AMERICAN BRIDGE BUILDING.—In a late address upon the public works of the United States, M. Malezieux, of Paris, complimented the American engineers upon their skill in building bridges of large span, and says that all other nations may borrow many useful hints from them in regard to the use of compressed air in laying foundations.

ON an English railway recently, on the occasion of a trial of the Westinghouse brake, a stop was made in a distance of 511 feet, with the train (passenger) going at a speed of 60 miles an hour. This remarkable feat was accomplished by the use of a special brake valve which kept the pressure on the wheels just below the sliding point.

FORM OF PROJECTILE FOR PENETRATING WATER.—Careful experiments have clearly proven that flat-ended projectiles penetrated both water and armor, at an angle, better than the hemispherical or the gothic end.

Standard Measures.

The standard yard, now in use in the United States, was taken from the English standard yard; but it was subsequently shown that this standard, as deposited in the office of weights and measures at Washington, was incorrectly taken off—it being 0.00005803 longer than the English imperial standard yard. This difference was no doubt due to incorrectness of the divisions on the original scale, or derived from insufficiently delicate appliances for reading off the measure from the English standard.

It cannot be expected that the divisions on the English scale could be very correct, from want of knowledge in those days to make a correct screw, which is yet a difficult problem, even with our advanced knowledge of mechanic arts. But as it was originally intended to have the English and American standards of length alike, we ought not to acknowledge any difference.

The Smithsonian Institution published tables in 1859, comparing the length of the English and American foot measures, which makes the American yard 2·1000th parts of an inch longer than the Imperial standard yard, or a difference of four inches *per mile*. The United States Coast Survey are now using a corrected American standard yard, the same length as the Imperial standard yard.

A STRANGE PEOPLE.—Dr. Siegfried read an interesting paper at a late meeting of the Philadelphia Academy of Natural Sciences, giving some account of an almost unknown and very strange people residing on the island of Botel Tobago, situated in the seas to the southward of the Indian ocean. This paper was founded on the report of a party of U. S. Naval officers, which recently visited those islands. The party was surveying a rock east of the South Cape of Formosa, and called at this island. They found a curious race of Malay stock. These aborigines did not know what money was good for. Nor did they ever use tobacco or rum. They gave the officers goats and pigs for tin pots and brass buttons, and hung around the vessel all day in their canoes waiting for a chance to dive for something which might be thrown overboard. They wore clouts only, ate taro and yams, and had axes, spears and knives made of common iron. Their canoes were made without nails, and were ornamented with geometrical lines. They wore the beards of goats and small shells as ornaments.

HOW TO SUCCEED AS A MECHANIC.—Every mechanic should study to be progressive. He should study to make every new piece of work a little better, in some way, than the last similar work which he has turned out. An eminent French coachmaker says: "I never build two carriages exactly alike, not because I do not build each one as well as I know how, but in building that I learn how to make the next one better. When I placed these carriages of mine in the exposition building, I thought them perfect, but now that I have spent three months looking over the carriages of other builders, I see that they are not so." Here is an illustration of the value of close observation and study.

A NEW DEVICE FOR CLEANING SHIPS' BOTTOMS.—Experiments have been made in England with the Archimedean revolving brushes for cleaning the bottoms of iron ships. It is self-acting, being worked by a revolving screw, the revolutions of which are regulated by the speed of the vessel. The brushes are made right and left, so as to strike the vessel with the current, and cleaning away all grass and slime without injuring the paint. It is the opinion of nautical men that during a voyage, were the machine to be used at intervals, the bottom of the vessel would be kept perfectly clean, and much time would be saved on the ship's passage.

USEFUL INFORMATION.

The Mysteries of a Lump of Coal.

For years no one supposed that a lump of soft coal, dug from its mine or bed in the earth, possessed any other purpose than that of fuel. It was next found that it would afford a gas which was combustible. Chemical analysis proved it to be made of hydrogen. In process of time mechanical and chemical ingenuity devised a mode of manufacturing this gas, and applying it to the lighting of buildings and cities on a large scale. In doing this, other products of distillation were developed, until step by step, the following ingredients are extracted from it:

1. An excellent oil to supply lighthouses, equal to the best sperm oil, at lower cost.
2. Benzole—a light sort of ethereal fluid, which evaporates easily, and, combined with vapor or moist air, is used for the purpose of portable gas lamps, so-called.
3. Naptha—a heavy fluid, useful to dissolve gutta-percha, India rubber, etc.
4. An excellent oil for lubricating purposes.
5. Asphaltum, which is a black, solid substance, used in making varnishes, covering roofs, and covering over vaults.
6. Paraffine—a white crystalline substance, resembling white wax, which can be made into beautiful wax candles; it melts at a temperature of 110°, and affords an excellent light. All these substances are now made from soft coal.

NEW MODE OF MANUFACTURING WHITE LEAD. A German paper gives a new process of making white lead, which is described as follows: The molten lead is poured through an iron sieve into a tank filled with water. Hereby it is converted into threads of one-sixth of an inch in thickness, which are now placed in vats, each of which holds about 1,000 threads. Vinegar is now poured over the lead, and immediately drawn off again. Under the influence of the air and the vinegar adhering to the metal, the latter is oxidized. The vinegar is now poured into the vat and again drawn off, when it carries away the acetate formed on the surface of the metal in solution. After this process has been repeated a number of times, the vinegar has been transformed into a concentrated solution of basic acetate of lead, from which the carbonate may be prepared by the introduction of a current of heated carbonic acid gas. The supernatant liquid is—mixed with another quantity of vinegar—used again for the same process.

BRONZING WOOD, LEATHER, PAPER, ETC.—The *Moniteur Industriel*, of Paris, describes a process for bronzing wood, leather, paper, etc., as follows: The inventor dissolves gum lac in four parts by volume of pure alcohol, and then adds bronze or any other metal powder in the proportion of one part to three parts of the solution. The surface to be covered must be very smooth. In the case of wood, one or several coats of Meudon or Spanish white are given, and the object is polished with an iron of proper shape. The mixture is painted on, and when a sufficient number of coats have been given, the object is well rubbed. A special advantage of this process is that the coating obtained is not dull, but can be burnished. A transparent varnish is applied to preserve the metallic appearance thus obtained.

HOW TO MAKE COURT-PLASTER.—Soak isinglass in a little warm water for 74 hours, then evaporate nearly all the water by gentle heat, dissolve the residue in a little proof spirits of wine, and strain the whole through a piece of open linen. The strained mass should be a stiff jelly when cool. Now stretch a piece of silk or sarsanet on a wooden frame, and fix it tight with tacks or packthread. Melt the jelly, and apply it to the silk thinly and evenly, with a badger hair brush. A second coating must be applied when the first has dried. When both are dry, apply over the whole surface two or three coatings of balsam of Peru. Plaster thus made is said to be very pliable and never breaks.

COSTLINESS OF FOOD.—Thousands of persons, we might say hundreds of thousands, in our great republic, begin life poor, live poor during life, and die poor because of the exceeding costliness of the foods they eat. Think of our eating butter at 35 cents a pound, when one can buy Indian corn at 60 cents a bushel. One bushel of hickory nuts has more oil in it than five pounds of butter. One bushel of Indian corn has more nutriment in it than $2 worth of the best beefsteak you can find. One bushel of real graham flour has more nutriment in it than a barrel of superfine flour and 50 pounds of beefsteak. We spend ever so much to live when it need cost us but little, and our health will be all the better.—*Exchange.*

A HAND coal-cutting machine has been introduced into some of the Pennsylvania coal mines, which, it is said, will cut seven yards face, to the depth of three feet, and making a cut only four inches wide, in one hour. It weighs 240 pounds. Can be used for heading, breast or shear. Requires no track; easily handled by one man, and does the work of ten. The reduced amount of slack as against pick is enough to commend it to every bituminous coal operator. It can be seen in operation at the Morris Run mines, where five machines are now at work.

SAFE AND CONVENIENT METHOD OF TESTING DYNAMITE.—The *Chemiker Zeitung* contains a description of a method of testing dynamite. The percentage of nitro-glycerine is determined by extracting it with ether, which dissolves it, but leaves the infusorial earth unchanged. The difference in weight of the dynamite and of the infusorial residue, directly yields the percentage of nitro-glycerine. In order to ascertain whether the dynamite contains any other bodies soluble in ether, the ether extract is diluted with water, which precipitates any foreign substances present.

HOW GASLIGHT IS LOST.—Computations of the loss of light by shades of different kinds have been brought together by Prof. Chandler, and are presented in a pamphlet entitled "How to Burn Gas." The lowest absorption of ground glass is nearly 30%; there is only one specimen at this low figure, other shades of that kind absorbing more than 62%. Opal glass causes a loss of 53% to 56%; green, purple and ruby glass, 82% to 89%; and a porcelain transparency, over 97½%.

PURITY OF MILK.—It is stated in a German paper that the purity of milk may be tested by the following very simple method: A well-polished knitting-needle is dipped into a deep vessel of milk and immediately withdrawn in an upright position; when, if the sample be pure, some of the fluid will be found to adhere to it, while such is not the case, if water has been added to the milk, even in the smallest proportions.

CEMENT FOR CAST IRON.—Five parts of sulphur, two parts of graphite, and two parts of fine iron filings, are melted together, taking care that the sulphur does not catch fire. The parts, previously warmed, are covered with the cement, reduced to a pasty consistence on a fire, and firmly pressed together. This cement, it is said, is very well adapted to fill out leaks in cast iron vessels.

GOOD HEALTH.

Olive Leaves as a Panacea.

The olive leaf or branch, old as the ark, woven into many of the sweetest tales of Palestine, descending at last the current ages until it becomes at length a sign of victory in the practical conquest of the earth by the agriculturist of California, has certainly glory enough for one plant. But it has other points of promise which our olive growers will be interested to know. We read in the London *Farmer* that the medicinal properties of the olive and its leaves are just now attracting considerable attention in Italy, and numerous notices of the employment of the plant for such purposes both in past and present times are going the rounds of the press. In the rural districts of Spain, it appears, the powdered leaf is very generally employed by medical men in cases of epidemic intermittent fevers. During the wars of Napoleon in that country, the French army surgeons, unable to obtain access to other medicines, made use of concoctions and extracts of olive leaves, in fevers and several other diseases, with encouraging success. The febrifuge properties of the leaf were proved by M. Faure, at the Strasburg School of Medicine, in 1814, and subsequently by M. Beguin, the military surgeon. In the Provence, astringent gargles, prepared from the leaves, are much used in relaxed and sore throats and similar complaints. The Arabs still pin their faith on a prescription given to them by the prophet, the observance of which is guaranteed to cure almost every disease. A hundred leaves of the olive are to be wrapped in a piece of cloth and applied to the forehead, and the fever or other disease will at once be subdued.

We should be slow to give the leaves the full force attached to them by the Arabs, but a little experimenting in the line followed in Spain and Provence would not be amiss.

A Warning to Plumbers and their Patrons.

Diphtheria, scarlet fever and pneumonia have been particularly active in certain parts of New York and Brooklyn during the past year, and the cause is criminal carelessness, official stupidity, and extraordinary recklessness on the part of property owners, and of builders and plumbers. Although the life of a person in ordinary circumstances is of as much value as the life of a millionaire, it is quite natural that the latter, dying in a costly mansion where money has been lavished on devices for protection and comfort, should attract the greater attention, especially if it were a reasonable inference that sewer-gas was in any degree a predisposing cause. Fortunately the death of the late Mr. Rockwell, in Brooklyn, was brought to notice of the authorities, and the result of an official investigation is most surprising.

When Mr. Rockwell's family began to die, and one after the other was carried to Greenwood, public attention was attracted to the several possible causes of this extraordinary fatality, but no one dreamed that the death-trap was the trap in the millionaire's costly but worse than useless plumbing.

The Sanitary Superintendent of Brooklyn examined the pipes and general plumbing, assisted by an expert. Among other things they found that some of the main lines of soil-pipe that are continued to the roof do double duty—carrying off the sewer-gas and acting as rain leaders. One of the pipes receives the water from 1,200 square feet, and during heavy rains is so filled with water as to empty every trap connected with it. The water closet in the bath room was found attached to this pipe, and its trap was so nearly emptied of water that it offered an obstruction to the entrance of sewer gas. Mr. Rockwell had wash basins in his sleeping rooms and nursery, but the traps do not hold water, so of course the gas had no difficulty in gaining entrance. In fact, if the builder had desired to turn his house into a hospital and furnish his own patients, he could not have devised a better system of defective plumbing.

A Theory in Regard Food.

The *Pall Mall Gazette* says: "A German physician has started a new theory with regard to food. He maintains that both the vegetarians and meat-eaters are on the wrong track. Vegetables are not more wholesome than meat, or meat than vegetables, and nothing is gained consuming a compound of both. Whatever nutritive qualities they may possess, he says are destroyed in great measure, and often entirely by the process of cooking. All food should be eaten raw. If this practice were adopted, there would be little or no illness among human beings. They would live their apportioned time and simply fade away, like animals in a wild state, from old age. Let those afflicted with gout, rheumatism and indigestion, try for a time the effect of a simple uncooked diet, such as oysters and fruit for instance, and they will find all medicines unnecessary, and each a rapid improvement of their health, that they will forswear all cooked articles of food at once and forever. Intemperance would also, it is urged, no longer be the curse of civilized communities. The yearning for drink is caused by the unnatural abstraction from what are termed 'eolids' of the aqueous element they contain—uncooked beef, for example, containing from 70% to 80%, and some vegetables even a larger proportion of water. There would be less thirst, and consequently less desire to drink, if our food were consumed in its natural state, without first being subjected to the action of fire. Clothing, our adviser also thinks, is a mistake, but he admits that the world is not yet far enough advanced in civilization to go about undressed. Whatever differences of opinion may exist as to this anti-cooking theory, there cannot be a doubt that in getting rid of the kitchen with all its abuses, including the cook, housekeepere would be spared a vast amount of worry, and probably on this account alone would live to a greater age than at present."

HOW A SEDENTARY LIFE AFFECTS WOMEN.—The *Popular Science Monthly* remarks that many of the ills and diseases prevalent among women in our days are no doubt traceable to the sedentary mode of life so common among them. The progress of industrial art has done away with much of the household drudgery to which women were formerly subjected, and the result is in too many cases want of sufficient occupation for needed bodily exercise. It says: The fruits of this state of things are strikingly exhibited in certain observations made by the late Dr. Robertson, a Manchester surgeon, who, in his practice as a specialist for women's diseases, found that in women who themselves perform all their household work there was no trace of certain complaints, that these complaints begin to make their appearance in women with one servant, become more pronounced in women who have two servants, or worse still in those who have three servants, and so on. He showed statistically that the deaths from child-birth were four times greater in the cases of women with four servants than those with none. On the other hand we observed a statement the other day that since the suspension of labor in the mills of New England on account of the panic, many of the female operatives have sought employment as domestics, and as a consequence there is much more sickness among them than there was previously. This would seem to show that housework is not as healthy as labor in cotton or woolen mills.—*Troy Times.*

ARE FAT PEOPLE HEALTHY.—Why are fat people always complaining? asks some one who entertains the popular though erroneous notion that health is synonymous with fat. Fat people complain because they are diseased. Obesity is an abnormal condition of the system, in which the saccharine and oleaginous elements of the food are assimilated to the partial exclusion of the muscle-forming and brain-producing elements. In proof of this, it is only necessary to assert the well-known fact that excessively fat people are never strong, and seldom distinguished for mental powers or activity. Besides they are the easy prey of acute and epidemic diseases, and they are the frequent victims of gout, heart disease and apoplexy.

MILK AS A SOPORIFIC.—According to the *Pharmacist*, it is a frequent practice in the New York Asylum for Inebriates to administer to the patients at bed-time a glass of milk, to produce sleep, and the result is often found satisfactory without the use of medicine. Medicine is there sometimes prescribed in milk. It has been recently stated in medical journals that lactic acid has the effect of promoting sleep by acting as a sedative, and this acid may be produced in the alimentary canal after the ingestion of milk.

The Week.

Small tidings of important developments in the mining regions or decisive fluctuations in the stock market, have reached us during the past week. Of the latter we remark that it seems thoroughly demoralized. Times may have been duller and prices lower with it, but seldom, if ever, has it been in as thoroughly stagnant a condition as now. The Sutro Tunnel compromise seems to have finally come to a definite settlement, with no likelihood of further trouble concerning its provisions. Mention of it will be found in another column. Testimony is still being taken hy the referee of the Alta-Justice case, concerning the conduct of the latter's officers. In spite of the abundance of water and other cheering prospects, the immediate outlook among the placer interests of some sections, is not a bright one. The injunction granted in the "mining debris" case expires on the 9th, and then all the placer mines on or around Bear river will be obliged to suspend work till the case is finally settled by the Supreme Court; and this discussion, together with certain apparently objectionable clauses in the new constitution, have been the grounds for the late shutting down of the Watt Blue Gravel and other placer claims in Nevada county. These stoppages have thrown a number of men out of employment and given discouragement to further prospecting in that part of the country. It is understood that the Chollar is soon to be divided into two mines, the Chollar and the Potosi, each to be represented by 112,000 shares, or eight of the new to one of the old. In other States the mining interests look extremely favorable, but from all the cry is heard for more capital with which to develop and extend the mines.

The Future of our Manufacturing Industries.

The condition of the English manufacturing classes is at the present time altogether woful; it is even desperate. For a while, these poor people, though unemployed, managed to subsist on the little savings of more prosperous times and the funds of their semi-charitable associations. But these resources are exhausted, and, what is worse, the prospect for any early or even ultimate improvement in their condition seems hopeless. The markets of the world, which England for so many years monopolized, are being closed to the products of her great workshops, her mills and her factories. She has, for some time past, been making more of these commodities than she could sell; they have accumulated on her hands, filling her vast warehouses with unsalable stocks and converting millions of invested money into dead capital. And the idle operatives on her hands too. But they, though dying, are not yet dead. It would be better, perhaps, if they were. But it is a slow process, this of starving men to death. The vitality of the half pauperized is wonderful. It surpasses that of the self-sustaining and even the well-to-do. A merely animalized man is apt to live long; and so they survive their wants, these compact, unwieldy masses, abject and hopeless, wallowing in misery and sodden with filth.

The spectacle of these vast populations reduced to such deplorable straights were enough to almost make one wish that no manufacturing pursuit would ever gain a foothold on American soil. And if these industries could be established only through such debasement and suffering it would indeed be well if the country could be kept wholly free from them. But such is not the case. We shall become a great manufacturing nation without brutalizing our operatives or starving them to death. We enjoy many natural advantages for the successful prosecution of these varied industries which England and most other countries do not. We possess or grow the raw material to a much greater extent than she does or can ever hope to do. In our numerous swift-flowing streams we have a cheap and widely disseminated propulsive power that she is without. Our iron and coal, and our other metals and minerals, as well also as our forests, our sheep lands and cotton fields, like our water-power, are illimitable and widely distributed, making it possible and altogether economical for us to scatter our manufacturing establishments all over the land; thereby avoiding what has proved the greatest curse to the English and entire European system—the concentration of many pursuits and consequently of many people at one point. Under this system our mills and factories will be more or less isolated, and the growing up of great, gloomy, pestilential cities be avoided. A few large manufacturing towns will no doubt come into existence, where, as at Pittsburg and some other points, extensive deposits of iron and coal occur in conjunction. But we will hardly have any such overgrown cities as Leeds, Birmingham or Sheffield on this continent. Instead of these great smoke-begrimmed towns, with their slums and foetid atmosphere, we will have numerous cleanly and well-lighted villages; substituting homesteads with their cottages and gardens for the great tenement houses and squalid quarters so common in those cities of the old world with their vast aggregations of people.

Even here in California we may hope to see great manufactures spring up and flourish at an early day. No country more invites the establishment of a system of diversified industries than this. Our wool product is already large, and we shall soon be growing cotton, and, perhaps, also flax, silk and other textile fibers, at a rate that will lead to the building of mills for spinning and weaving these staples into fabrics on a very extensive scale. In the foothills of the Sierra we have water power ample for driving all the machinery in the New England States. And the rivers and creeks that afford this power are not confined to a narrow space. They extend over a stretch of country more than 500 miles long. These streams, which furnish hundreds of eligible and easily accessible mill sites, traverse what must become the great cotton fields of the future. Short branches over easy grades would connect these mill sites with the railroads that now traverse the State almost from one end to the other along the great interior valleys. Buildings could be cheaply constructed at all these points, the country adjacent being well timbered. Here is also the finest fruit growing region in California, the agricultural and wool growing capacities of the country being at the same time very considerable. There is no more beautiful or healthful country than this in the world, and why, with so many natural advantages, it should not in time become a great manufacturing district it is difficult to conceive.

And these reasons that are appliable to this section of California, apply with more or less force to most parts of the United States. Everywhere the manufacturing can be scattered amongst our other industries, and, thus intermixed, all productive pursuits be made mutually beneficial and supporting. While sanitary conditions would be immeasurably promoted, great social and economical advantage must inevitably grow out of this arrangement. England is obliged to import at great cost the breadstuffs and most other food required to feed her factory operatives from abroad. We raise all this at home, and could, therefore, afford to furnish subsistence to this class of populations at much lower rates. By creating courts of conciliation and arbitrament for settling all questions that arise between employers and workmen, by encouraging to the early adoption of the co-operative principle, and by the studious avoidence of the many abuses that have grown up in older countries, we shall, no doubt, be able to build up and sustain in the United States a great system of manufacturing industries, without this English accompaniment of starving operatives to become, alike a reproach to our civilization and a peril to the republic.

Caution and Encouragement to Eastern Mine Investors.

There is now a great deal of unemployed money in the East. This is especially true of the Middle and New England States. The active employers of capital there have for many years been investing largely in railroad and petroleum stocks and in the prosecution of various commercial enterprises and manufacturing pursuits. Banking, gas and insurance companies, together with a great variety of minor industries, have also absorbed largely of their available means. Although profitable for a time, these various branches of business have come to be overdone. Very few of them can any longer be made even fairly remunerative. Competition and over-production have glutted the markets and reduced profits to a very narrow margin or extinguished them altogether. While such is the state of affairs with the more practical and useful callings, in the purely speculative lines of business the condition is even worse, the bold and wealthy having gained such complete mastery here as to render operations by all others futile or exceedingly dangerous.

In this strait the moneyed men of the East are casting about for new enterprises and other fields in which to embark a portion of their idle capital. They naturally direct their attention towards the great mineral regions of the far West, knowing well that there exist here innumerable good openings for making money. They know that the Pacific States and Territories abound with gold and silver-bearing deposits; that our annual product of the precious metals approximates a hundred million dollars and that great numbers of people have been immensely enriched through mining ventures. But they know another thing—they know that nine-tenths of the money invested in our mines on Eastern account have proved a dead loss to the investors; and knowing this they hesitate about embarking their means in a business that to people abroad has turned out so disastrously.

We say people abroad, because it is useless to deny that non-resident investors in mining properties on this coast have, as a general thing, fared worse than those living on this side. The reasons for this are so natural and obvious as to require no explanation. Parties at a distance buying mines through middlemen, often inexperienced and always interested to deceive the purchaser, are, of course, greatly liable to be imposed upon. Between ignorance and design they are almost sure to be victimized. And, for that matter, those domiciled on this coast, miners themselves included, have, through injudicious investments of labor and money, suffered in the aggregate more loss than all other classes combined, these losses having been due in the main to want of experience or other excusable or unavoidable causes, not a few, also, to foolish experiments, hazardous ventures and willful mismanagement; these latter having been of much more frequent occurrence during the early history of this industry than of late.

Mining for the precious mentals was a business that the American people had to learn throughout, and generally under very unpropitious circumstances. But we have at last mastered it pretty thoroughly, and will hereafter be likely to avoid most of the errors of the past. The present is therefore a good time for those who have hitherto kept aloof to embark in this business. They enter upon it at a time when labor is comparatively cheap and abundant, when person and property are everywhere adequately protected by law, when transportation and travel have been cheapened and expedited through the construction of wagon roads and railways, and when they can enjoy all the advantages growing out of thirty years of energetic experimenting and lavish expenditure made to develop and advance the business.

To such of our Eastern friends then as contemplate engaging in this branch of mining we would say this is a favorable time to start in, provided, of course, they intend to pursue it in a practical, business-like way. If they enter upon it with only speculative aims we don't see why an Eastern railroad or an oil well would not answer this purpose equally ae well as a gold or silver mine. For stock gambling they ought to be able to find something nearer home that would serve their end sufficiently well. But of this they are the best judges, and if inclined to get up something for the Eastern share market it is not for us to seek to dissuade them from looking for it in this quarter. Presuming, however, that these parties desire to engage in actual mining and to carry it on in a legitimate way, we respect, they never could have started in at a better time; and if they will only observe the same caution and economy in the conduct of this that they have always considered necessary in every other kind of business they will not be disappointed in their reasonable expectations.

In making choice of a field for mining operations there are some reasons why California should perhaps be selected in preference to any other part of the coast. In the first place, we have here a greater variety of mines from which to make a selection, our metalliferous resources not being confined, as in most of the other Pacific States and Territories, to vein deposits alone. We have several different kinds of placer diggings that can be worked to great advantage, as well also as silver-bearing lodes and auriferous quartz in the greatest abundance, the latter being worked at the present time with more satisfactory results than any other mines in the country. In California almost our entire mining region is traversed or closely skirted by railroads, rendering it easily accessible both as regards freights and travel. The climate is such that mining operations can be comfortably and successfully prosecuted at all seasons of the year, it being, in fact, every way one of the finest in the world. Labor, machinery and supplies of all kinds are cheap in this State and easily commanded. After much experimenting we are able to reduce our ores at a moderate cost and with considerable closeness, our quartz-crushing machinery and gold-saving appliances having been brought to much perfection. We have, in short, cheapened the business and reduced it to greater certainty than has anywhere else been done, notwithstanding the State of Nevada has of late years turned out a larger annual product of bullion than California.

Without enlarging on this point, it is enough to say that California presents as many and as good opportunities for the investment of money in mining as any other section of the coast. From San Diego to Siskiyou, a distance of more than 700 miles, there is scarcely a county along the main gold belt but contains quartz mines of real value, and which could be bought for a nominal sum and he worked with profit. In all the more central and northern of these counties occur the various forms of placer deposits alluded to, and in which interests can also be obtained on terms that no one wishing to engage in this branch of mining could reasonably object to. This region opens an immense field for steady, quiet, profitable mining, nearly all the conditions here being exceedingly favorable.

The people of the East often express surprise that, of all the mines opened and equipped here, so few should, through their large and profitable bullion production, become noted abroad. It should be remembered, however, that there are in California some eight or ten thousand men who make good wages working their own claims in a quiet and limited way, but of which nothing is ever heard. Then there are numerous small associations and incorporated companies who make much larger earnings, though operating in a way equally quiet and unheard of. It is not the policy of these parties to make a noise about what they are doing. Generally speaking, it is only those who have some object to be gained thereby, who seek to give publicity to their operations. Very little do outsiders know about some of the most successful mines in this State. Some of these properties are owned by one or two individuals, or, perhaps, by a small number of partners who have not thought it worth while to incorporate; or who, if they have done so, have never procured their shares to be listed on the stock boards, a proceeding that is apt to prove detrimental to the best of properties by creating two sets of antagonistic interests, one concerned to enhance and the other to depreciate the value of their shares.

A person not conversant with the laws and usages that govern in the mining districts, might be lead to ask why it is that the owners of these valuable claims are willing to sell them at such very low rates instead of retaining and working them themselves? The answer is that under the general laws and local rules regulating these matters, it is possible for a man to establish and maintain possessory ownership to a great number of these mining claims or locations, even though he be without the means to open and put them in shape for active production. All that is required to keep good his title, is the performance of a certain and not large amount of work each year. This done, and he can hold on to them year after year, or till such time as he can make sale of them or find some one who will furnish means for developing and outfitting them for a part interest therein. Sometimes the owner of a productive claim will sell it at a moderate figure to get money to open and rig up another claim belonging to him. Occasionally good bargains may be got because the owner, through sickness or advancing years, or for some similar reason, may wish to leave the mines. Through these several causes there is never a lack of properties to be had on favorable terms, either in California or elsewhere in the mining regions. Let but the Eastern purchaser proceed with his usual caution, buying only after thorough examination and seeing to it that the business is conducted in an honest and capable manner, and he will have abundant reason to be satisfied with his investment in the mines of this coast, whether he embarks his money in the gold-bearing deposits of California, the silver-bearing lodes of Utah or the mixed mines of our other Pacific Coast possessions.

The Snake River Placers.

From a conversation recently had with Mr. J. A. Jacobs, an owner in several productive claims on Snake river and from the letters of correspondente there, we are in posseesion of much fresh and reliahle information touching the condition and prospects of placer mining along that stream. The gold-hearing depnsits extend for a distance of two hnndred miles or more along the Suake, that is to say from the vicinity of the Malad river to Blackfoot and abovo. As a general thing the farther down stream the richer the ground appears to be in gold. This is contrary to the opimione first entertained, and seeme to argue that the gold has heen contrihnted hy the country along the river and nnt brought down from its upper tributaries, along which the hars aleo pay moderately well but not like thoee farther down.

While there is probably a little gold in the surface earth ovor a hroad belt of country lying adjacent to the river, there is enough only in tho bars along the stream to pay for washing. These bars are of two kinds, first those which occur in the deep canyone, and eecondly thoee formed along the flat country through which the river passes. The former, though the more prolific in gold, are comparatively emall, lie low, extendiug down into the water when the rivor falls to its lower etages, and being overflowed when it ie swollen by the melting of the snow on the mountains, which occurs in the monthe of May and June. Theee hars constituted the sites of former operatione, the gold here having heen more plentiful and perhape a little coarser than elsewhere, thereby enahling the pioneer miners to make fair wages washing at first with the rocker and afterwarde with ordiuary sluices. The hars in tho flat country where the river epreads out are generally large, some of them covering hundrede of acree, their eurfaces being from 50 to 200 feet ahove the stream. It ie on theee that the principal operations are being carried on, though the others are also heing worked on a smaller scale.

These larger hars do not, as a general thing, yield gold throughout. Indeed, this is not the case with any of the extremely high onea. Usually there occurs on top a pay etratum from 25 to 30 feet thick compoeed of loose dirt, eome of it much mixed with alkali. Below thie, two or three feet of harren cemented gravel ie met with, not so hard, however, hut that it can he run off with water. Then comes in a hed of clean gravel from 15 to 20 feet thick, and richer than that on top, thie heing underlaid hy a heavy hody of reddish sand, harren and extending, it ie suppoeed, to the hedrock. Not even in all of the higher hare do these eeveral etrata occur, nor yet alwaye in the ahove order.

Already everything along the river that promises to he of any value and a great deal that does not has heen taken up. In proceeding with this husinees the miners after their usual custom have organized districts, elected recordere, and adopted for each a eet of rules to he oheerved in locating and holding claims, which latter are limited to an area of twenty acres each. The washing is done with sluicee, which vary from one to four feet in width according to the quantity of dirt to he put through and the amount of water to he had for washing. The eize of the eluice is, however, apt to depend more upon the amount of the miner's means than other conditione, the quantity of the eilver-coated copper platee, an expeneive item, heing in proportion to the eize of the sluice. These plates coet in thie city ahout $5 per equare foot. On a four-foot eluice running 100 or 150 inches of water from four to five hundred square feet of these plates are employed, while on a one-foot eluice running from 20 to 30 inchee of water only ahout 35 square feet of platee are ueed. At first large eluices with much water were preferred, but latterly the tendency ie to smaller ones as favoring a closer eaving of the gold. The minere there, through constant experimenting with their machines, are all the while slightly modifying their apparatus or the manner of using it. The latest change to he noted in thie connection ie the euhstitution of entire silver platee for the kind now in uee, and which though more costly it ie thought will prove much more effective.

The most distinguished feature of this branch of mining ie the great economy of labor of which it ie eueceptihle, a single man in moet casee heing eufficient to attend properly to the operations of a eluice, whatever its eize; only two men, on alternate shifte, are therefore required to a machine, washing goiog on day and night. Two companies operatiog near each other could get on with a working force of hut five men, four to attend to the sluicee and one to do the cooking. At cleaning up it might he convenient for the eingle man to have some aseietance, hut at other times it is not required except where the dirt is shoveled into the eluices, ae is practiced on the low-lyiog emaller hare, and eometimes aleo on the larger. Generally, however, the force of the water discharged from hoee or narrow wooden hoxes, is eufficient to carry the gravel into and along the whole length of the sluice, the dirt heing eo looee as to require no etirring up after it is once in tho machine. The expenee of outfitting a claim variee from one to three or four thoueand dollars, thie including building cahin, coet of sluice, tools, hriuging in water, etc. Water is brought on the claims through ditches, taking it from the river or its tributaries where this is practicahle. In other cases it is raiscd hy current wheels and carried through troughs to tho points where required for use.

The gravel along Suake river usually pays from $10 to $25 per day to the haud, some claims doing much hetter and others uot quite so well. Occasionally a clean up is made with the larger sluices that paye at the rate of $20, or $30 and even $50 per day to the man.

"LONE PEAKS," ON THE ROAD FROM EHRENBURG TO PRESCOTT, ARIZONA.

As the original coet of outfitting a claim here is not large and the ground will laet for a long time, variously eetimated at from five to twenty yeare, thie ie likely to prove a very attractive and profitable branch of mining. A large eluice will put through from 300 to 400 toue of dirt per day, and the emaller a proportional amount.

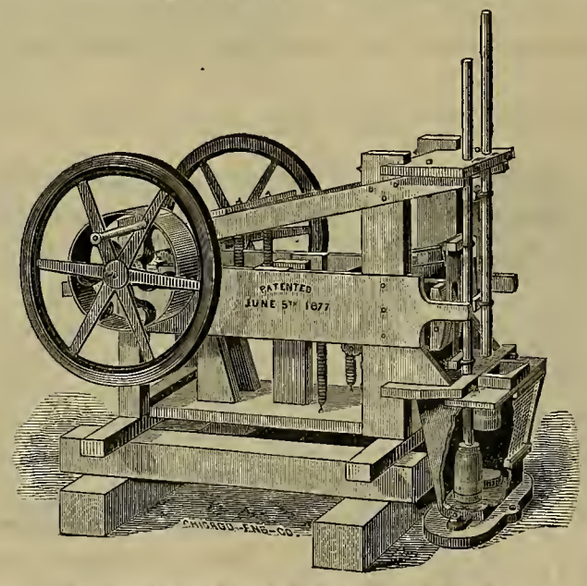
The pricee of claime vary, of couree, with their eize, richneee and the facilitiee at hand for working them, the circumetances of the seller having also very often something to do with the husinees. In some iostaoces claims have heen sold for not more than $50 or $60, while again they will eell for eeveral thousand. Mr. Jacohs telle ue that a tract situate near the Malad and consisting ot eeveral claims with good water privileges, eold lately for $6,000.

From the preceding it will be seen that there is not much use of a man, without eome pecuniary meane, going to these Snake river minee, as everything worth taking up is already claimed and held at pretty stiff prices, while there is hut little demand for labor even at the lowest prices. The wages paid there are $1.50 per day of twelve hours, board inclnded, or $2.50 per day without; monthly wages $42 to $60. Tho coet of living in that region is rather high, for whilo heef and potatoes and eome other things produced there are cheap, all imported articles are dear, owing to the long wagon transportation to which they are subject. The price of passage from San Francieco to these mines will vary from $60 to $80, etage fare from Kelton on the Central Pacific railroad to the river, 135 milce, heing $20.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Standard, March 25th, $17,759; Bulwer, March 25th, $18,284.10; Northern Belle, March 24th, $8,023.37; Alexander, March 28th, $10,-162.08; California, March 29th, $41,132.36; Con. Virginia, March 29th, $28,277.94; Martin White, March 31st, $15,025; Ophir, March 29th, $11,274.14; Grand Prize, March 31et, $8,200; Independence, March 31et, $5,500; Standard, March 21st, $15,502.36; Bulwer, March 31et, $17,777.18.



HAND OR POWER PROSPECTING QUARTZ MILL.

SALMON have commenced to run in Puge sound.

A WORLD'S fair is to he held in New York in 1883.

"Lone Peaks" in Arizona.

We take from "Pictnreeque Arizona," by E. Conklin, another glimpee at the peculiarities of Arizona scenery. In his account of theee wondrous prominences on the level face of the country, the anthnr says:

The eecond night out from Yuma hronght us to "Antelope Peak," a famone camping spot, and so named from a high towering peak jutting up from the ground in magnificent and haughty style, and ehrouding you and the camp grounds eurrounding, with its casting ehadows. An adohe huilding for the stage company's office, and a corral for the protection and care nf the horses, and the graceful flow of the Gila river, o'ershadowed by the towering "Antelope," constitute the main attraction for the camper. It is a very refreshing and cooling retreat for the traveler, whn hae had juet enough of the sand and eun of Arizona hy thie time, to appreciate and enjoy it. Thie peak, inetead of being called a peak, having the features nf eo much of the Arizona mountain ecenery, would be better comprehended hy being termed an ieolatcd mountain; jutting, as it does from the very level of the plains, and throwing iteelf grandly up to a hight of hundrede of feet into nne single conical-ehaped formation. There are several of theee entertaining fellowe over the plaine of the Territory, relieving the eye of mnnotony, and without which the deeerte and the traveler on them wonld yearn for eome eociety. Their extreme contrast with the eurroundinge, exalting them to a glorious standard. One of the moet hold and pleasing of theee peaks ie tn he eeen on Stewart & Peareon'e stage road from Ehrenherg to Preecott. After riding for miles and hours over the hroad eandy plains, with the distant monntaine forming a pleaeing encloeure to a vast natural etage upon which many a weird and midnight ecene has been enacted, to come boldly upon these two lone peake (there are two of them) standing eide hy side, is a scene worth the whole ride. As the stage paeees hy close to their hase, they look down frowningly upon you; and were you euperstitioue, would almoet think they spoke to you in the etarry etillnees of the night.

The occasion which I firet saw these peake wae in the middle of the night. It wae a hright moonlight one, and the hazy light of the moon from hehind, throwing the shadow far over our etage coach, produced a eombre effect. Beholding these two giant figuree o'erepreading me as it seemed, I was held with awe for a few minutes, and then said to the driver, "What are these?" at the same time holding my face up at right angles to eee the top.

"Oh! those?" said he, in a quiet unconcerned voice,—"Oh! those are stonee that grow here in Arizona." I named the peake "Lone Peake," ae agreeahle to the circumstancee and conditione, ae well ae the sentiments of hoth myeelf and my friend the driver.

A Hand Power Quartz Mill.

We give on thie page a representation of C. Eaton'e patent "Poor man'e prospecting hand or power quartz mill." It ie eimple and durahle, and so constructed that two men can operate it all day. The force of the hlow can he changed eo ae to etrike a light or a very heavy hlow, readily. It can be run hy hand or power, a band pulley heing put on as ehown, for the latter purpose.

When power ie ueed the manufacturers inform us that each etamp will etrike 150 hlows per miute; and that the force of the blow in compariecn to the face of the etamp (4½ inchee) ie greater than any of the heavy power stamps. Theee machines are well made, heing put together with holts, to he taken apart readily, so as to he convenient to pack on a mule'e hack. The whole machine weighs ahout 1,300 pounds, the heavieet piece weighing 200 pounde. The engraving eufficiently explains the method of operation.

The revolution of tappete on the crank shaft depreee the inner ende of the levers, which raiee the etampe hy meane of etraps paseing over the outer ende of eaid levers. The other end of the etrap or cord faetened to the etamp ie secured to a ratchet wheel, hy which meane it is poesihle to regulate the drop. Spiral epringe draw down the levere ae they are released hy the came, so ae to cauee the etampe to strike the hlow.

The caeh price of this machine ie $150; for sale at the Ames Steam Engine Depot, 14 South Canal street, Chicago, Ill.

SINCE the Central Pacific Co. put eleeping-care on the road for the accommodation of emigrants the emigration weetward has materially increased, four or five car-loade coming through daily.

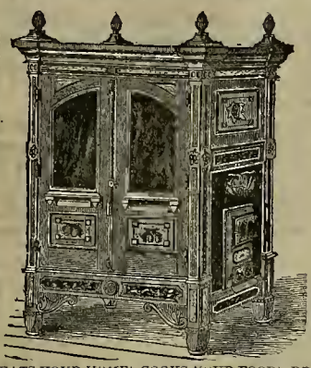
THE latest report gives the number of miles of railroad in New York at 5,752, of which 4,358 are douhle track.

THERE are general complaints in the country that the printed Conetitutions are elow in reaching the people.

WORK hae been reeumed in the tunnel where the explocion took place, on the Southern Pacific railroad.

Boswell Heater, Cooker and Drier.

COMBINED FOR FAMILY USE.



OPERATED BY DEFLECTED HEAT.

HEATS YOUR HOME! COOKS YOUR FOOD! DRIES YOUR FRUITS, Etc. Economizes TIME, LABOR and FUEL, and AVOIDS EXPOSURE TO HEAT IN COOKING.

In WARM WEATHER, when COOKING or DRYING, the HEAT and ODORS can be PASSED UP THE CHIMNEY; and in cold weather the heat can be regulated to any desired degree evenly throughout the house. Food cooked by DEFLECTED HEAT contains more nutriment, is more easily digested, will keep fresh longer, and is much improved in flavor and appearance. Will dry and bleach clothes in half an hour, and heat the irons, thus saving the WASH-WOMAN FROM EXPOSURE while hanging them out in stormy weather or cold rooms.

Fruit dried by DEFLECTED HEAT will gain from 20 to 40 PER CENT. IN WEIGHT, and 30 PER CENT. IN QUALITY over that dried by radiated heat or in the sun.

Requires but ONE-THIRD the quantity of FUEL used in any other heating apparatus.

Mine Wanted.

The advertiser is prepared to purchase a *good* California Gold mine; gravel or quartz. Must be in a condition to be examined and prospected.

Send full particulars, description, location and price to "MINER," care of Chas. O. Yale, Esq., editor of the MINING AND SCIENTIFIC PRESS, San Francisco, Cal.

Picturesque Arizona. By E. CONKLIN, Representative of the National Associated Press, and artist and correspondent of Frank Leslie's publications. Being the result of Travels and Observations in Arizona during the fall and winter of 1877. Fully illustrated. Sent by mail, post-paid, for $2. Address DEWEY & CO., 202 Sansome Street, S. F.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and placer mining in various parts of the Pacific Coast. Over five hundred orders have been filled, and the demand is constantly increasing. A large number of these Plates were sent to Snake River mines, Idaho, last year, and a great many orders are being filled for them this season. Circulars containing full instructions for working these Plates sent with each order. Old Mining Plates bought or taken in exchange for new Silver Plated Plates, and full value allowed. Gold extracted from old Plates at a moderate cost by a new and economical process. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed.

Mining Men and the public generally are cautioned against unprincipled and irresponsible parties traveling through the country, endeavoring to secure orders for very inferior qualities of Silver Plated Mining Plates.

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,
North Bloomfield, Nevada Co., Cal., October 1st, 1878.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.
The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

[Continued from page 213.]

fourth level is now in 60 ft, ths ore assaying $178 to the ton. In ths second and third levels there is no change in ths quantity of ore. The amount of ore in sight at present is larger than ever before, and the quality is also improving. The south tunnel level is now in 290 ft. The last 50 ft of this level has been run through a solid body of mineral, the face in high-grade ore.

ARIZONA.

GLOBE DISTRICT.—*Silver Belt*, Mar. 29: The Alice shaft is now down 113 ft, and in four ft six inches of good ore, which samples 192 ounces. The mineral is both widening and growing richer each shot. A crosscut was commenced at 110 ft, and the headcr is now 14 ft from ths footwall, all the way in low grade quartz, with a marked improvement as the hanging wall is approached. Three and one-quarter tons unassorted El Capitan ore, worked at Miami mill 152 ounces. The Golden Eagle mine of Gold Hill, is said to improvs under recent work. There is a shaft 78 ft deep, and in a drift at the bottom there is a five-ft vein that prospects very well in gold, the estimate being about $75 per ton.

TOMBSTONE.—Cor. *Citizen*, Mar. 29: The Lucky Cuss main shaft is down over 50 ft; it was sunk vertically, cutting into the vein at 30 ft from the surface and is still in a fine body of ore. The north shaft is turning out some of ths finest ors that has been exposed for a long tims. At the west cut on the hill can he seen the ore that makes frequent $1,000 buttons. On the Old Guard, the first north extension of ths Lucky Cuss, a 40-ft prospecting shaft is under way, revealing a fine vein of from one to three ft in width. The Contention main shaft is down over 90 ft, and Supt. White expects to make connection with the 113 level from the south shaft in about 10 days.

COLORADO.

LEADVILLE.—Cor. *Tribune*, Mar. 26: The mining fever seems on the increase rather than ths wane. Hundreds of prospectors have gone out this week, and not a few of whom have seen their labors rewarded by discovery of metal in paying quantities. Gold-bearing quartz has been found in California gulch, but whether in paying quantities, or in such amounts as will warrant active working, it is impossible to state. The Bruce iron mine, situated on Stray Horse gulch, has been sold during the past week to parties said to reside in Leadville, for $80,000. The property comprises three or four located mines, among which are the William Penn, Philadelphia, General Cadwalader, and Benjamin Franklin. Nearly all the best paying mines are not doing what they might do, if the prices paid for ore would warrant it. At least twice as much ore could be taken from the mines and good profits realized therefrom, but the companies believe they can hold the ore until better facilities for transportation can be had, and get better interest for their money. The moment railroad transportation reaches Leadville, 50 mines will be worked to a profit where there are five worked now. It is extremely difficult to ascertain, with accuracy, the amount of ore mined in and about this camp per day. There are probably about 15 to 20 mines that average an aggregate of 500 tons of ors per day. Not all of this ore is smelted or even disposed of by the parties taking it out, for the process of smelting, under the present disadvantages of high freights and uncertain transportation, is so costly, that nearly all the profits are eaten up in converting the ore into bullion. There are dumps or places of deposit at all the mines, where nearly all the ors below a certain grade is deposited, to await the time when smelting will be cheaper. It costs nearly if not quite 33½ more to reduce ore to bullion now than it would if the roads were good and freights reduced to its legitimate basis. All this extra cost is, of course, deducted from the purchasing price of the ore. Kokomo continues to attract the excited miner and speculator. Some very good discoveries have been made in the vicinity of Jack mountain, about a quarter of a mile north of the town. Specimens were exhibited here that show rich in silver with some traces of gold. Some of the holes are from 20 to 30 ft, and in many of them there is considerable trouble experienced from water.

MONTANA.

MINING ITEMS.—*Miner*, Mar. 25: During the past winter the main shaft on Mr. Stinson's claim on the Stevens lode was sunk to something over 60 ft deep, or a little below water level. From that point a level was run eastward following the ledge for 50 ft, and another west for 35 ft, when stoping was begun. From the stopes Mr. Stinson is taking ore of three grades, the lowest grade yielding from 60 to 70 ounces per ton; the second about 100 ounces, while a lot of first-class was sold on the dump for $150 per ton. At present the dump contains 250 tons of ore, of which 30 tons is first-class, 100 second, and the balance third-class, or 60-ounce ors. In consequence of the strike in the Alice, the main shaft on the claim will immediately be sunk 250 ft deeper, or to the total depth of 550 ft from the surface. The pumps now in service will be quite equal to the task imposed upon them by the deepening of the shaft; but to cut the ledge at the 500 level will require additional machinery, already ordersd from Salt Lake City. The ore in the 300 level being of so much higher grade, and what is still more important, so much less base, than that of the 200 level, but little doubt is entertained respecting the developments to be made deeper down. Mr. J. K. Pardee, Superintendent of the Algonquin mining company, has purchased the Salmon mine from its former owners, Messrs. Holland & Estell, paying therefore the handsome price of $50,000. Having made this investment, the Algonquin Co. will proceed to the immediate erection of a 20-stamp mill, to be provided with Howell roasting furnaces, and in other respects to ressmble the Allce mill, at Walkerville.

OREGON.

BAKER COUNTY MINES.—*Oregonian*, Mar. 29: Recently a contract has been let to sink a winze 50 ft, commencing at the west drift of the Discovery. Going down a few feet with the winze, a 10-inch vein of very rich ore was found on the foot of the wall, showing much native silver, the ore on the assay showing 65% silver. The contractors are going down slowly owing to ths water flowing in. The winze is now down 20 ft, showing the 10-inch stratum of 65% ore to be increasing in thickness, with every indication of a rich and extensive body of ore in the vicinity of the winze. Another contract is let and being worked on for a drift running east, showing excellent pay rock with every sign of its continuing. The tunnels now run ars too close to the surface to admit of working to the best advantage. What is now required to make the mines yield a large dividend is the necessary machinery for hoisting works, with a vertical or inclined shaft ths depth of 500 or 600 ft, with additional stamps for the mill and a good substantial roasting furnace or two. There are other mines here as rich as the above. The Lafayette gold and silver lode, situated about three-fourths of a mile from the Discovery claim and on the same ledge, has furnished hundreds of tons that have paid as high as $100 a ton in gold. A company of miners are now engaged in extracting very rich ore there, to be crushed at the mill on the Discovery claim, and other rich and extensive mines are lying idle on account of there being no custom mill or roasters in the neighborhood to work the quartz.

THE 2,500 tons of railroad iron for the Northern Pacific are being shipped from New York.

FORTY-EIGHT employees of the Carson Mint were suspended Mar. 31st, till further orders.

THE Russian exploring expedition to the Merv has been stopped.

The Sutro Tunnel.

Final Settlement of Differences Between the Tunnel and Mining Companies.

The final proceedings respecting the agreement between the Sutro Tunnel Company and the Comstock mine owners have at last been taken and the papers signed, sealed and delivered. At Virginia City and Sutro, salutes were fired, and bonfires kindled as tokens of rejoicing over the long-delayed consummation of the agreement. Work on the tunnel sub-drains will be immediately commenced and some 2,000 men set at work. Mr. Sutro expects that the mines will begin to use the tunnel within sixty instead of ninety days, as provided in the agreement. He estimates the daily output of ore, after the mines are drained, or connections with the tunnel made, and crosscutting under way, will average 3,000 tons, of which 2,500 will probahly belong to that class yielding under $40 per ton, on which a royalty of $1 per ton will be paid, and 500 to the class yielding above $40, on which the royalty will be $2. Besides there will he some revenue for transportation, furnishing timber, compressed air, water power, etc.

Although the papers signed by the companies vary somewhat in detail, they are all practically alike, and are to the following effect: The preamble speaking of the original agreement entered into in March, 1866, with the Gould & Curry Silver mining company, declares that all mines on the Comstock lode are heneficially interested in a speedy completion of lateral tunnels, and are desirous of adjusting all their differences. The argument is substantially as follows:

"Article first says that the terms of the agreement have heen complied with hy all parties.

"Article second says that the main tunnel is considered as coustructed according to the terms of the agreement, but provides for the construction of a covered drain to carry off all water, of whatever temperature, within 90 days.

"Article third provides that until the end of 90 days no water shall be discharged into the tunnel; but after that period, or sooner, if a drain is ready, the mines shall be at liberty to dnmp any water into the tunnel, including the water used in the mines for propelling power.

"Article fourth provides for the construction of lateral tunnels—one to the north, running first to about 100 feet west of the C. & C. shaft; thence to about 100 feet of the Sierra Nevada shaft, and thence about 500 feet east of the Utah shaft. To the south, heginning at the Julia shaft, which is already connected with the main tunnel, and running to about 80 feet east of the Yellow Jacket shaft, and thence to about 200 feet west of the new Overman shaft. These lateral tunuels are to he begun within 90 days, to be well constructed, 3 feet wide by 7 feet high, and to he pushed ahead with due diligence.

"Article fifth makes provisions for deflecting from the regular course of the lateral tuunels in case unfavorable ground is encountered.

"Article sixth says that the mining companies agree to advance $70 per foot for lateral tunnels, payments to he made at that rate on the fifth day of each month for work done during the preceding calendar month. Each of the companies has a right to construct a lateral tunnel hefore its own claim and receive credit therefor at the same rate.

"Article seventh provides for the repayment of these advances hy allowing the mining companies to deduct one-half of the monthly charges on ore reduced or sold, until the amount advanced is repaid.

"Article eight provides for the reduction of charges on ore from $2 to $1 per ton on ore yielding $40 per ton, a ton heing 2,000 pounds.

"Article ninth provides that mines lying hetween the California on the north and the Chollar-Potosi on the south shall he considered drained whenever the tunnel is ready to receive water from the mines now connected with it. The mines north of the California or south of the Chollar are to he considered drained as soon as the lateral tunnels reach their respective centers.

"Article tenth provides for the mining companies furnishing a sworn return of their product each month at each mill, with the actual yield in bullion, and for the payment of charges thereon hy the tenth day of the succeeding month.

"Article eleventh provides that no mine shall allow any other mine, which has no agreement, to discharge its water so that it could he pumped into their tunnel.

"Articles twelfth, thirteenth and fourteenth provide for the construction of an outside parallel drain, if it shall at any time become necessary; that all agreements are to he deemed to he of the same purport, and that all articles are to he hindiug upon each party and their successors or assigns forever," etc.

NOT less than $1,000,000 of capital is invested in grounds and buildings of the East Liverpool, Ohio, potteries, and it is estimated that fully 1,200 persons are employed in the various factories, while many more are sustained by this industry in the miuing of clay, etc.

THE Paris exhibition buildings will be entirely demolished, and the Champs de Mars relegated to its old occupation as a drilling ground.

News in Brief.

LOUISIANA bas had seven Constitutions.

BERKELEY is troubled with cattle thieves.

OPIUM smoking is on the increase in Nevada. stand.

TROY DYE, the Tullis murderer, is becoming insane.

THE tramp nuisance is on the increase in Fresno.

MOKELUMNE indulges largely in sturgeon fishing.

LITTLE WOLF'S band of Cheyennes has been captured.

CHINA has made a demand on Russia for territory.

PRAIRIE fires are committing great ravages in Dakota.

GERMANY approves the joint occupation of Roumelia.

FOUR HUNDRED Ohio miners have struck for bigher wages.

POVERTY FLAT is now the richest section on Salmon river.

THERE is a strong call for wives among Western farmers.

THERE is a great deal of partisan excitement at Washington.

CHINESE gambling bouses are being found in New York City.

TRICHINOSIS seems to be becoming common all over the world.

OREGON complains of the prevalence of commercial "drummers."

THERE were 905 English soldiers killed by the Zulus at Isandula.

FOUR Italians have been poisoned with mushrooms at Mendocino.

CALIFORNIA cheese hrings 12½ cents a pound in the Prescott market.

AMERICAN canned goods are to be found in nearly all parts of Asia.

SEVERAL Indian chiefs, including Moses, are en route to Washington.

THE Willamette river, Or., is still rising and a flood is anticipated.

THE woman suffrage hill failed to pass the Massachusetts Legislature.

SUPERIOR coal has heen found at South Boulder canyon, Colorado.

PHOTOGRAPHERS are taking pictures at night hy means of the electric light.

THE arrival of a Chinawoman at New York has created quite a sensation.

THE New Orleans banks have resumed the payment of currency on demand.

OPERATIVE weavers at Blackburn have voted to accept the five per cent. reduction in wages.

A RUSSIAN Countess has heen arrested at St. Petersburg for sympathizing with the Nihilists.

A SEATTLE jury has awarded three cents damages in a slander case. Costs of case, $500.

FROM the light fall of snow a scarcity of water is predicted at Virginia City, this summer.

THE rival medical schools are fighting over the composition of the National Board of Health.

OPIUM smuggling from British Columbia into the United States has become an American industry.

THE New Mexico papers are filled with announcements of discoveries of rich mineral districts in various parts of that Territory.

A GANG of 14 men are engaged in retimbering portions of the Sutro tunnel in places where the ground is soft and unstable.

A NEW BOOK ON THE COMSTOCK LODE.—We have received from John Wiley & Sons, scientific hook publishers of New York city, a circular announcing a forthcoming work entitled the "History of the Comstock Lode," by John A. Church, M. E., professor of mining in the Ohio State University. It is to be in one quarto volume well illustrated by maps and engravings. The author will attempt to show the mode in which the great silver deposits were formed, and will explain the true position of ore hodies in the lode, the relation of rich to harren quartz, the reason for the concentration of ore in particular localities, the channel by which the quartz entered the lode, and the true zonal arrangement of the rich and harren grounds, exhihiting the cause of the long-continued poverty of the portion now worked and the prospect of future improvement. Prof. Church arrives at the conclusion that the mines are by no means exhausted, but that they have a great future before them. The price of the hook will be $6 to those who send in their names before the work is ready for issue; after it appears, the publishers say the price will he advanced. Subscriptions for the hook will be received by Dewey & Co., 202 Sansome street, S. F.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's offics at San Francisco:

ARMSTRONG O. M. Co.—Object: To operate in Butts county. Capital, $500,000. Directors—J. S. Rawlins, C. Stevens, P. Amiraux, J. W. Pew and William Armstrong.

AMEER M. Co.—Object: To mine in Bodie district. Capital, $10,000,000. Directors—Thomas Price, A. J. Ralston, J. P. Allen, D. L. Parkhurst and R. H. Brown.

BOSTON S. M. Co.—Object: To mine in Alpine county. Capital, $10,000,000. Directors—L. O. Cole, H. W. Redington, George E. Maguire, C. F. Moulthorp and James Biddolph.

CENTRAL STAR O. M. Co.—Capital, $2,000,000. Trustees—Robert J. Creighton, Edmund B. Kilhorne, William F. Drake, Charles H. Howland and S. Wilson Church.

MONTE CRISTO CON. M. Co.—Object: To operate in Mono county. Capital, $1,000,000. Directors—J. D. Thompson, J. M. McDonald, Clinton Gurnse, L. Shoris and B. F. Bivins.

CARRIE STEELE M. Co.—Object: To operate in Utah. Capital, $10,000,000. Directors—John F. Miller, Louis A. Garnett, O. H. LaOrange, J. F. Cronise and O. C. Miller.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Diepatch from Washington. D. C.

FOR THE WEEK ENDING MARCH 11TH, 1879.

213,032.—BUFFER SPRING—Wm. M. Betts, S. F.

213,174.—WATER GAUGE AND ALARM—O. Collier, Sacramento, Cal.

213,177.—GUIDE FOR STEMS FOR STAMP MILLS—C. Crane and W. Raup, Park City, Utah.

213,096.—ENGINE—J. H. Darragh, S. F.

213,194.—NOZZLE FOR HARDENING DIES—J. B. Harmstead, S. F.

213,206.—BREAD BOX—W. O. Jones, San Joss, Cal.

213,055.—CAR COUPLING—J. C. McCollum, Wilmington, Cal.

213,154.—IMPROVEMENT IN CONSTRUCTION OF BRIDGES—E. Williams, S. F.

213,153.—CAR BRAKES—A. Weymouth, Livermors, Cal.

213,117.—AXLE FOR VEHICLES—E. E. Lincoln, San Jose.

213,052.—IMPROVEMENT IN LAMPS—D. Lubin, Sacramento, Cal.

213,134.—IMPROVEMENT IN DENTAL PLUGGERS—H. Richmann, S. F.

7,196.—LUBRICATING COMPOUND—Trademark—Dean, Oraccy & Co., Virginia City, Nevada.

——This patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Forsign Patents furnished by DEWEY & Co., in ths shortest time possible (by telgraph or otherwise) at the lowest rates. All patent husiness for Pacific coast inventors transacted with perfect security and in the shortest possible time.

A LAND-SLIDE on the Lehigh Valley railroad tbrew a locomotive of a New York train from the track, killing its engiueer and fireman.

A MORMON mob captured Tooele conuty, Utah, and controlled elections to suit themselves.

THE negro exodus from Louisiana continues.

SOUTH PACIFIC COAST RAILROAD.—This popular line has made a reduction in rates betwsen San Francisco and San Jose and Santa Clara, to take effect April 1st, 1879, viz: Regular local tickets betwcen San Francisco and San Jose, $1.75; Santa Clara, $1.65. Round trip tickets (good until used) between San Francisco and San Jose, $3.25; Santa Clara, $3.05. Excursion tickets sold Saturday afternoons and Sunday mornings from San Francisco and Park street, Alameda, to Santa Clara or San Jose and return, $2.50; good only until Monday evening following date of purchase. Commutation tickets good for one round trip daily during calendar month, between San Francisco and San Jose, $20; Santa Clara, $19. Family tickets for 10 rides and 30 rides, also six months and yearly commutation tickets on sale at corresponding reduction in rates.

ORO. H. WAGGONER, Gon'l Pass. Ageut.
THOS. CARTER, Superintendsnt.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Oruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by *letter*.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Lifo Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of Insured, 224 Sansome St., San Francisco.

M. D. SHRADER is now an authorized agent of the PACIFIC RURAL PRESS, also MINING AND SCIENTIFIC PRESS, to solicit subscriptions and receive the money for the same His receipts given for such money will be duly honored by this company.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 416 Market St., second floor, S. F.

Chew JACKSON'S BEST Sweet Navy Tobacco.

And in accordance with law, and an order of the Board of Directors, made on the 21st day of January, 1879, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the Company, No. 330 Pine street, Room 48, San Francisco, California, on the 26th day of March, 1879, at the hour of one o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

O. M. CONDEE, Secretary.

Office, Room 48, No. 330 Pine St., San Francisco, Cal.

POSTPONEMENT.—The above sale has been postponed until Saturday, April 5th, 1879, at the same hour and place. By order of the Board of Trustees.

O. M. CONDEE, Secretary.

Mount Jefferson Milling and Mining Com-

pany.—Location of principal place of business, San Francisco, California. Location of works, Garrote Mining District, Tuolumne County, California.

Notice is hereby given, that at a meeting of the Directors held on the 21st day of March, 1879, an assessment (No. 6) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, Room 6, No. 318 Pine street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 2d day of May, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Tuesday, the 27th day of May, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

R. N. VAN BRUNT, Secretary.

Office, Room 6, No. 318 Pine Street, San Francisco, Cal.

Summit Mining Company.—Location of

Principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 7,) levied on the 4th day of February, A. D., 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Byers, W T	38	700	35 00
Edwards, J E	39	700	35 00
Gautier, Gustavo	156	200	10 00
Kellogg, H W	46	1000	50 00

Lehmann, C, Trustee	207	200	10 00
Turner, J W	65	200	10 00
Thompson, R	24	1200	60 00

And in accordance with law, and an order of the Board of Directors, made on the Fourth day of February, A. D., 1870, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, No. 318 Pine street, Room 6, San Francisco, California, on Tuesday, the Eighth day of April, A. D., 1870, at the hour of three o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

R. N. VAN BRUNT, Sec'y.

Office, Room 6, No. 318 Pine Street, San Francisco, Cal.

POSTPONEMENT.—The sale of delinquent stock of the above named Company is hereby postponed until Tuesday, the Sixth day of May, 1870, at the same hour and place. By order of the Board of Directors.

R. N. VAN BRUNT, Secretary.

Office, Room 6, No. 318 Pine street, San Francisco.

The California and Oregon Land Company.

—Location of principal place of business, San Francisco, California. Location of Works, State of Oregon.

Notice is hereby given, that at a meeting of the Board of Directors, held on the First day of March, A. D., 1879, an assessment (No. 2) of Forty Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, Room 6, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 10th day of April, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Saturday, the Tenth day of May, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

R. N. VAN BRUNT, Secretary.

Office, 318 Pine Street, Room 6, San Francisco, California.

Union Stone Company.—The Regular

Annual meeting of the Union Stone Company of California for an election of a Board of Directors (to act as Trustees) to serve the Company for the ensuing year, and for such other business as may properly come before the meeting, will be held at the office of the Secretary of the Company at 237 First Street, San Francisco, California, on Tuesday, April 8th, 1879, at 11 o'clock A. M.

R. F. KNOX, Secretary.

San Francisco, March 20th, 1879.

STEVENOT'S

Fine Gold Amalgamator.

Adapted for Ores, Tailings, Slimes, Etc.

Unequaled for Cheapness, Lightness and Practical Results.

No mechanism required to run it. Worked entirely by pressure of water throwing the ore forcibly on to and through a body of mercury.

E. K. STEVENOT,

Chemist and Mining Engineer,

304 Montgomery St., San Francisco.

THE SAFETY POWDER COMPANY,

San Francisco, Cal.

CARTRIDGE.

GEN. W. S. ROSECRANS, President.

Fuse Lighter and Fuse.

COL. SAM'L O. GREGORY, Secretary.

Safety Cap and Fuse.

Electric Cap.

Safety Powder, Caps, Electric Caps, and Fuse Lighters.

Under a series of U. S. Patents, after long and carefully conducted experiments and thousands of tests, this Company is prepared to manufacture and supply, for Mining and Engineering Works, the above named articles at prices and on terms as favorable as articles of similar grades are now supplied in this market. Our Powders contain no Nitro-glycerine, no Nitroline, no Gun Cotton, no Fulminates, and are free from the unavoidable dangers in manufacturing transporting, handling and using of all high grade explosives which contain those elements.

Cold does not affect them. They cause no headaches or other inconveniences in handling, and the smoke from their explosion contains no poisoning or sickening vapors.

Their blasting force, with slight tamping, at least equals that of any Powders now used, but they admit and require strong tamping to bring out their immense and peculiar lifting power which follows their detonating work. They should be fired, therefore, by our

Safety Cap,

Which allows tamping without danger. They can be fired by any caps now employed in blasting, but the use of these is always dangerous with any Powder, and the loss of the throwing power resulting from lack of tamping renders it with our Powders doubly objectionable.

Our SAFETY CAPS have twice or thrice the force of triple Giant Caps. When set on fire they do not explode, but merely burn off, and are perfectly safe in transporting and in tamping.

In round tin boxes, 50 cents.

The Safety Fuse Lighter,

Cheap, handy and sure to light the Fuse upon the end of which it is fastened, only needs a trial to be appreciated by every miner who is up to "snuffs." 25 Cents per box; sent by mail.

Safety Fuse,

Equal to the best in the market, will be supplied at the lowest market prices.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature, thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

VOLUME XXXVIII Number 15.

DOUBLE SHEET—24 PAGES.

An Arizona Mining Camp.

In our double sheet edition this week we give due prominence to matters relating to the new mining country to the southeast of San Francisco, embracing Arizona and the Mexican State of Sonora. These regions are being brought close to us by the advance of the Southern Pacific railroad and lines of travel connecting therewith. Our readers will find on nther pages an able article on the mineral resources of Sonora by an engineer whn has had long experience in the region which be describes. Another valuable contribution to the growing literature concerning Arizona, will be found in one of a series of articles writtcn for the PRESS by Capt. W. H. Seamans, who has lately returned from a protracted tour through the Territory. This article is illustrated by a map of tbe Big Bug mining district, wbich is described.

By way ot varyiug the character of the Arizona matter which we present in this issue, we give on this page an engraving of interesting views in the Territory. One is of an Arizona mining camp, the location of tbe works of the Toltec Syndicate. The engraving is fron Conklin's "Picturesque Arizona," which accords considerablo space to tbe resources and operations of this company.

The Toltec camp is in the Aztec district in southern Arizona. The engraving shows the characteristic vegetation of tbe region and the style of tbe buildings wbicb mark young camps. Concerniug tbe section in whicb the Toltec is located, we cannot do better than to quote from Col. R. J. Hinton's "Handbook of Arizona" tbe following paragraphs:

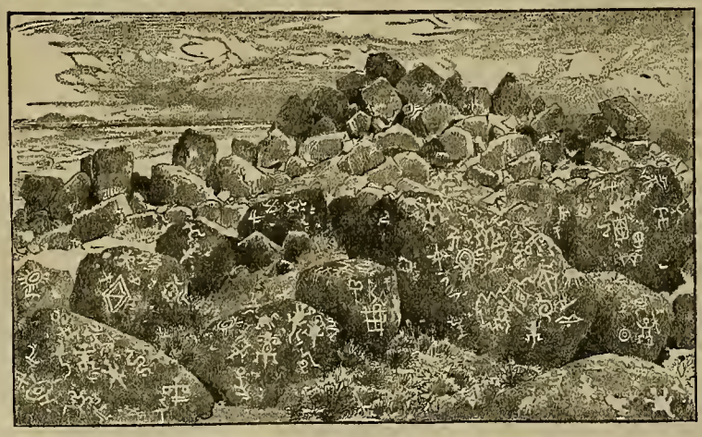
The road to the Toltec camp, now a busy little center of mining activity, and for the time being the working head quarters of the Aztec Syndicate's operations, whence everything connected witb the works on the Aztec, Inca and Iturbide mines is directed, branches from the Tumacacori wagon road at some distance west of the old Hacienda. Crossing another deep and rough arroyo, down which during the rainy season quite a body of water pours, it passes for about three miles over a comparatively level mesa, rising gradually and having a more rugged aspect than the route up from the Mission. It is flanked on the west side by high castellated cliffs, bold and striking in form, of dark porphyry and white tufa, and on the other side by the south-by-east spur of the range itself. As you journey, upon the right the eye notes the fantastic outlines of the high colored bluffs, and takes in a hroad expanse of country, far beyond tbe Sonora line, and embraces the Oro Blanco on nne side and the Patagonia's dim outlines on tbe nther. Cacti become numerous, while the dwarf oak and mesquite remain abundant. Toltec camp lies at an elevatiou of 3,000 feet, in a small valley made hy the slopes of tbe range. Opening up to the southwest is the mouth nf a small but remarkable canyon, and towards the north leading up, the arroyo follows the range into a bewildering network of mineral lodes and veins. In May, 1877, the only sign of precediug activity visible was a little adobe house with a small nre heap near by. There is considerable and increasing evidence of industry now-a-days. The valley affords space for a mining town which is already beginning to grow thereat. The waters that come down from the mountain, cutting and wearing tbe granite, bave strongly defined the arroyo, and passing some distance beyond the camp, have cut a passage througb the immense quartziferous ledge on whicb the Empress of India lode has been traced, and falling down a distance of 200 feet form a cool deep pool below, which is apparently fed also hy a living spring. It has never yet been found dry even in the hottest of seasons. Tbe water has worn a deep cleft tbrougb the adamantine rock, looking down whicb the eye can readily detect strongly defined indications nf the presence of mineral veins. The Aztec district contains a large number of mines, located hy the Syndicate and hy private prospectors. It commences at the east end of the Empress of India mine, runs west of north along the eastora boundary of Tyndall, thence due north two milcs, thence due east three miles, thence due south six miles, and from there westerly to the point of starting. Everything possible is favorable to cheap mining and rich ores.

We also give on this page a view of objects of historic interest, the "painted rocks," which

THE TOLTEC MINING CAMP, AZTEC DISTRICT, SOUTHERN ARIZONA.

Mr. Conklin secured for his "Picturesque Arizona."

Mr. Conklin's account of his observations on the painted rocks is as follows: One of the leading features of interest to the traveler in the mesa laud of Arizona is the system of pre-historic landmarks be is constantly coming in contact with on all sides. Man has, as yet, however, derived very little positive knowledge of them from any research or investigation, and



THE PAINTED ROCKS OF ARIZONA—Pedras Pintados.

they remain to this day a source of speculative interest to the traveler, from the time he leaves the Colorado, at Yuma or Ehrenberg, uutil he completes bis journey. It is in these features that Arizona presents herself as the land for the archæologist, the psychologist, and all curious minds. Among the foremost of these are the "Painted Rocks" (*Pedras Pintados*).

About six miles from Oatman's Flat, on an extensive plain, encircled by the famous Arizona mountains, is to be seen the largest and most perfect specimens of these Painted Rocks (*Pedras Pintados*). They are in tbe Gila valley, 120 miles from Tucson, latitude, 33°, longitude, 113°. To stop and examine these wonders of the pre-historic age, is only to enhance the great enchautment that waylays the traveler in Arizona on every hand. They are a mass of rocks, evidontly piled by some physical power, ages ago. They are massed tngether in a beap about 50 feet high, with a proportionate base; and wbile some are of a size tbat may be lifted by a man, otbers might he ranked with boulders. On these rocks or stones, are various figures and images. Figurcs, geometrical, comic, and anatomical. There are squares, circles, triangles, crosses, snakes, toads and vermin, men without beads, and dogs without tails.

DIVIDEND-PAYING MINES WANTED. — Tbe New York *Mining and Engineering Journal* says there is a market in the East for sound, dividend-paying mines, and the shares of such properties, hut none whatever for mines badly managed or of duhious merit. Eastern investors have had enough of these and seem even more averse to having anything further to do with them than the people of this coast.

SIERRA NEVADA MINE.—Instead of controlling that property, as had been generally supposed, it is now stated that the Bonanza firm do not own any of the Sierra Nevada stock, the active assistance extended by this firm to Skae, at the time the latter entered upon a more vigorous development of tbe mine, baving lead to the above belief.

Gold on the Skagit.

The finding of gold on Skagit river, Washington Territory, although announced as a recent discovery, appears not to he an altogether new thing. As we learn from Prof. Amos Bowman, who is familiar with that country, gold mines, both placer and quartz, have been known to exist there for a number ot years. Several quartz mills have, in fact, heen running in the country east of the Cascade range for some time, and the Indians living on the upper Skagit, when coming to the towns on the sound to trade, have long heen in the babit of paying for their purcbases witb gold dust. The whites, in prospecting, also found gold along this stream, but not enough to warrant them in stopping to gather it, therefore it was concluded that they had failed to strike the locality where the Indians had obtained their dust, which was coarse and of good quality. This place has, most likely, at last heen found, and the discovery announced as one freshly made.

The Skagit river, which heads in the Cascade mountains, and runs west, emptying into Puget sound, is navigable for sixty miles, affording easy means for getting up near the mines, wbich, however they may pay fair wages for a sbort time, are probably nf no great extent.

The country east of the Cascades is auriferous in spots, all tbe way from Samilkanim river south to the Peshastin. In tbe northerly part of this belt, are situated the Kootenai mines, worked from the time of their discovery, in 1859, more or less for ten or twelve years, and which though they lie just over the line in British Columbia, have heretofore been approached, for tbe most part from tbis side, up the Columbia river. The Skagit, heing navigable for so long a distance, and flowing clean across the Cascades, through a low pass, will most likely be the route taken by the emigration to the region east of that range hereafter. Parties going in from Puget sound will, of course, proceed by this route. The Skagit Pass, lying so low, and being hut little obstructed, was one of those selected for the passage of the Northern Pacific railroad through the Cascade mountains, and is as likely to be the one finally adopted for that purpose as any other.

CITY HALL SANDSTONE.—Some time ago a reputable member of the Real Estate Protective Association made an allegation to that body, that worthless or unfit stone was heing used in the construction of the new City Hall. The matter was taken in hand by the executive committee, and at a meeting of the Association held on the 5th inst. a partial report on the subject was made. Several samples of the rock were examined by the association, especially that alleged to be used for keystones and arches. The stone was very brittle and friable, can he crushed in the fiugers, and dissolves rapidly in water. The following letter from Mr. Thomas Price, a well-known scientist, was also presented: "The rock you sent me to-day for inspection and opinion as to its value as a building stone, has been examined carefully, and I have no hesitation in pronouncing it a very poor article, and such as I would not recommend any one to use for building purposes. Disseminated through the mass are particles of clay that would tend to crumble the already soft rock on the slightest pressure. I do not thiuk tbat this rock would harden on exposure—that is to a sufficient extent so as to make it valuahle as a building stone." The stone is taken from a quarry on the Almaden road, five miles from San Jose. The results already obtained were deemed sufficient to justify a more extended investigation, and the matter was again referred to the committee, who will report fully at the meeting two weeks hence.

THE old railroad depot at Sacramento is soon to be replaced by a larger and more ornamental one.

The Genesis of Cinnabar Deposits.—No. 2.

[A paper read before the Geological Section of the California Academy of Sciences, by S. B. Christy, Ph. B.]

Third—Experiments on the Solubility of Mercuric Sulphide.

The great objection to accounting for the deposits of cinnabar in the wet way has always been the difficulty of finding any solution existing in natural waters capable of dissolving this substance. The experiments of R. Weber, cited above, show that as soon as the free alkali is neutralized, either by carbonic or sulphydric acid, the mercuric sulphide is precipitated completely from its solution in alkaline sulphides, and as free alkali is not known to exist in any mineral waters, the question has still remained: "In what has this substance been dissolved if we are to suppose it to have been formed in the wet way?"

The classic researches of Daubree‡ on metamorphism, and those of De Senarmont§ on the formation of metalliferous veins in the wet way, as well as the fact that these solutions must have acted originally at higher pressures and temperatures than those of the atmospheric waters, led me to carry out the investigations which I present to your notice.

Impressed with the idea that a moderate increase of pressure and temperature might possibly bring about the desired results, I was led to adopt a more easily manageable apparatus than that used by the investigators already meutioned. For this purpose I used a Papin's digester of gun-metal about seven and three-quarter inches high, three and a half inches in outer diameter, and five-sixteenths of an inch thick. This vessel was calculated to stand with safety a pressure of 650 to 700 pounds per square inch. It was provided with a safety-valve, so that the pressure could be easily regulated at any point. It was heated in a bath of iron filings, so that the temperature could be approximately determined as an additional check. The whole was surrounded by a sheet-iron shell to guard against danger from explosions. The digester was heated by an ordinary Bunsen burner. The substances to be experimented upon were enclosed in glass tubes, usually sealed at both ends, but occasionally open at the top, so as to allow the contents to slowly evaporate under pressure after the water had evaporated from the digester through the safety-valve.

The only disadvantage from using this form of apparatus was the difficulty of determining when the water was entirely evaporated. This led to several explosions of sealed tubes within the digester, and the consequent loss of many days' work. The joints were all made with a lead packing, as paper, leather, etc., would not resist the high temperature at which the experiments were conducted.

The highest temperatures reached were in the neighborhood of 250° (482° F.) The thermometer at the bottom of the bath of iron filings indicated 360° C., and at the top 150° to 200° C. The first experiment made was with a tube with a solution of amorphous mercuric sulphide and potassic sulphydrate. The tube was open at the top and its contents allowed to evaporate under a pressure of 150 pounds per square inch after the water had evaporated from the digester. The temperature was about 180° C. The operation was continued five hours. The liquid contents of the tube were reduced to one-half. The sulphide was entirely changed to a red powder, and the next day the tube was found to contain a beautiful coherent mass of crystals of cinnabar, recognizable by the naked eye and simulating the crystals which occur in nature very perfectly. They appeared to be rhombohedral, like the natural mineral, although I have not been able to determine this with certainty.

Subsequently a large number of experiments were made, all with closed tubes, upon various solutions, for the purpose of determining the action of the different reagents. The temperatures varied from about 200° to 250° C., and the pressures from 260 to over 500 pounds per square inch. The determination of the pressures were not entirely exact, owing to the difficulty of making the valve seat bear with perfect uniformity. The duration of the heating varied in the different experiments from three to ten hours, and in each case the digester with its contents was allowed to cool undisturbed till morning. The results of these experiments are as follows:

Solutions of sodium bicarbonates did not change the amorphous variety of mercuric sulphide to cinnabar. Solutions of water glass were equally powerless, but when through either of these solutions sulphydric acid was passed and the tubes were again treated in the digester the transformation took place. Polysulphide of potassium as well as sulphydrate changed the amorphous sulphide very rapidly and completely. The presence of carbonic acid seemed to retard the formation without being able to prevent it. The cinnabar formed was usually in the state of micro-crystals, like vermilion, but often they were larger and more like the native cinnabar in appearance, though they were so minute as to make the determination of their crystalline form extremely difficult. In all cases where the transformation had taken place the liquid would stain the skin deep black, as is usual where mercuric sulphide is dissolved in alkaline sulphides. This would be an additional proof, if one were required, that solution had taken place.

Finally, I was led to try the effect of heating the amorphous sulphide with New Almaden Vichy water, to which sulphydric acid had been added. This water as analyzed by E. Picquet, Mining and Scientific Press, Vol. 18, p. 360, has the following composition:

Bicarbonate of soda	50.3 grains.
Bicarbonate of lime	8.0 "
Sulphate of lime	16.5 "
Sulphate of magnesia	3.0 "
Chloride of sodium	8.4 "
Oxide of iron	1.2 "
Silica	traces
Carbonic acid	28.2 "

This amount was contained in one bottle of two pounds.

Sulphydric acid was passed into this water for half an hour, an equal amount of the mineral water and some black mercuric sulphide was added to it, and the mixture was treated in the digester, while a similar experiment was carried on at the ordinary pressure of the atmosphere, and 100° C. The temperature of the digester was not more than 180° C., and the pressure 140 to 150 pounds. The time in both cases was two hours. The sulphide which was treated in the open air was unchanged, even when examined with the microscope, while that treated in the digester was brownish red, even to the naked eye, while under the microscope it showed itself to be composed of a mixture of a small amount of, as yet unchanged, sulphide, and a larger amount which was completely transformed to cinnabar. Crystals were not visible with the powers used.

This mineral water, therefore, with the addition of the single ingredient of sulphydric acid, is capable, when heated, of dissolving and transforming mercuric sulpbide, and depositing it from solution in the crystalline form when it is slowly cooled.

Fourth—The Relative Probabilities of the Rival Theories.

Without attempting the impossible task of tracing the salts of mercury through all their successive changes, from their existence as vapor in the nebulous mists, to their present position in the existing ore deposits, it is, nevertheless, altogether probable that they would be precipitated from solutions in some form or other, at a period very soon after the globe had cooled down to a point which would allow them to exist in solution, and they would occur in some insoluble form, very probably as sulphide in the very earliest sedimentary deposits, and consequently would, if their position had remained unchanged, now exist at such a depth beneath the present surface, that man would never have known of such a metal as mercury. But as the sedimentary deposit increased in thickness, the deposits being cloaked at these points to a greater degree would be invaded by the interior heat of the earth, and according to the sublimation theory, would at last become so hot that the sulphide would become changed to vapor as soon as the pressure was relieved at any point on the sudden creation of a fissure by any mechanical agency, and then the vapors escaping through these fissures, would, by their elastic force, rise upwards until they reached a cooler locality, where they would be slowly deposited. It is, of course, impossible to settle such a question by observation, but reasoning *a priori*, it is probable that such action would take place under these circumstances.

The sudden invasion of igneous rocks among such sedimentary deposits would also cause a similar action if fissures above existed, capable of releasing the tension of the vapor and of furnishing the lower temperature necessary for condensation.

Even granting this to be a possible case, it is altogether improbable that such action is connected in anything but an indirect way with the genesis of the existing ore deposits, with the possible exception of the invasion of igneous rocks extending nearly, or quite, to the surface. This latter condition is certainly not the rule, but the exception; and even when it does exist, there seems to have been subsequent agencies active in giving rise to the deposits as they exist, which are not igneous.

In support of this position are the following facts:

In the first place cinnabar volatilizes only at just below a red heat (about 500 C.) when exposed to the ordinary pressure of the atmosphere. It is a well-known fact that the increase of temperature as we descend into the earth from the surface is about 1° C. for every 100 feet. At this rate of increase it would take a depth of nearly 50,000 feet, or about nine and a half miles to give this temperature. Now at New Almaden where the associated rocks are certainly not igneous, we find the cinnabar outcropping at the surface. This hypothesis would, therefore, necessitate the removal by erosion of nine and a half miles of superincumbent strata. The recent age of these rocks (pronounced Cretaceous by Prof. J. D. Whitney, Geological Survey of Cal.) evidently precludes such an hypothesis. Furthermore, the theory that the heat produced by the crumpling of the strata would be sufficient is not well founded, since the action usually takes place so slowly that the heat produced is dissipated by conduction to such an extent that the temperature can never be greatly increased at any one time. If we assume that the rate of increase of temperature was three times what it is at present, we still should have to go to a depth of three miles before any such temperature would be reached.

Not only so, but at such great depth the enormous pressure of the superincumbent mass would of course greatly increase the temperature necessary to volatilize the cinnabar. This fact is illustrated in the well-known case of water. The natural rate of increase of temperature of the earth is not sufficient to convert the water into steam at the existing pressure excepting in the presence of local igneous rocks, as is shown by the following table taken from Pfaff's *Geologie als Exacte Wissenschaft*, p. 112:

Depth In feet.	Temperature Centigrade.	Pressure of Water In Atmospheres.	Tension of Steam In Atmospheres.
10,000	100	300	1
20,000	200	600	15.3
80,000	800	2400	1416
100,000	1000	3000	1877
200,000	2000	6000	2403

The third column gives the weight in atmospheres of a column of water of a hight equal to the depth; this is the minimum pressure to which a substance can be exposed, unless we suppose an extensive fissure filled only with air and extending from the given point far upwards. The fourth column gives the tension of steam at the temperature correeponding to the depth, calculated according to Regnault's formula. It is evident that under these conditions the water will never become hot enough to boil at the existing pressure except in local cases where there are eruptions of volcanic rocks. Although there have not been, to my knowledge, any determiuations of the elastic force of cinnabar vapor it is probably less than that of steam, and the above reasoning will apply with even greater force to this case than it does to that of water, always excepting the cases of extensive fissures and the presence of volcanic rocks.

In the next place, the deposits themselves, as indicated in our study of the principal cinnabar deposits, do not usually show the signs of true fissure veins, but are rather found irregularly disseminated in layers and impregnations, and volcanic rocks are not usually found in sufficient proximity to give the amount of heat requisite to cause the sublimation.

In the third place, the formation of many of the ore bodies cannot be explained upon the sublimation hypothesis. Many of them, notably that of New Almaden, contain carbonates so intimately mixed with cinnabar that the conclusion is irresistible that they were formed *in situ* in the wet way. The occurrence of quartz and bitumen intimately mixed shows the same thing.

Again, M. Kuss,* himself evidently inclined to the sublimation hypothesis, admits regarding the Almaden deposits: "The material of the quartzite which is wanting to-day in the rocks impregnated with cinnabar, certainly could not have been missing, either at the time of the first deposit of the beds or after the strong pressure which compressed and straightened them. How could this disappearance of siliceous matter be effected; matter unattackable by all the reagents which we can imagine to have intervened during the epoch of the formation of the veins of cinnabar?" This disappearance of siliceous matter is certainly inexplicable by the sublimation theory, but by the supposition that the cinnabar was deposited from solution in a mixture of alkaline sulphides and carbonates, it would be not only explained, but also would be a perfectly natural consequence of the main supposition.

Still, again, all the minerals mentioned as occurring with the various ores of mercury in the first part of the paper; such as iron pyrites, blende, galena, fahlore, copper pyrites, etc., quartz, heavy spar, calc spar, dolomite, spathic iron, gypsum, etc., have all been produced in the wet way by De Senarmont and others. The production of bituminous material similar to idrialite has also been accomplished in the same way by heating organic matter with water in closed tubes at high temperatures.† In fact this transformation is invariably regarded, not as the result of dry distillation, but as the effect of heat in the presence of water. And, if the pressure was great enough to volatilize the cinnabar, it is probable that the much more volatile hydrocarbons of the original organic matter would have disappeared, and we should have *anthracite* or *graphite* instead of bitumen, as we do in most of the cinnabar deposits.

In addition to this, we have shown that the sulphide of mercury, at comparatively moderate temperatures, is dissolved by solutions of alkaline sulphides, even though in the presence of carbonic acid, that pressure aids rather than retards this solution, and that cinnabar is deposited from it in cooling. In one case we have shown that by adding sulphydric acid to the mineral spring water now existing in the neighborhood of one of the most noted of these deposits, we were enabled to produce the same effects. For various reasons, which it is needless to state here, it is probable that this spring once contained sulphydric acid, and we have therefore, in the case of the New Almaden mine at least, a sufficient cause for the deposit without invoking the sublimation theory.

Again, the occasional occurrence of metacinnabarite is easily explainable by the sudden dilution of the depositing waters by other springs, by fresh water from above, or by the local mixing during the crystallizing process with carbonic or other acid gases. No other theory so well accounts for the intimate mixture of the two varieties, crystalline and amorphous, so well described by Moore. (*Ueber das Vorkommen des amorphen Quecksilbersulphids in der Natur.*)

Finally, the almost universal occurrence of these deposits in metamorphic rather than in true igneous rocks accords well with the theory that these deposits *in situ* are the immediate result of the action of alkaline carbonates containing also alkaline sulphides.

There are still many other points of interest in this connection which are difficult to understand. Such, for example, are the wide-spread association of serpentine and other magnesian rocks, and of the bituminous substances with cinnabar. It is possible that these are conditions as well as mere concomitants. Lastly, there remains the occurrence of native mercury to be explained. Unless we regard it as the effect of the local oxidation of a very stable compound its appearance is well nigh inexplicable upon either hypothesis.

Relative Economy of Gas and Electricity as Sources of Light.

The Report of the Commission of the Municipal Council of Paris, furnishes the *first authentic data* in relation to the economy of the working of the electric light in that city. A Jablochkoff lamp is estimated to give a quantity of light equal to 11 gas lamps, consuming each 140 liters per hour. Hence, the quantity of gas consumed to produce the same quantity of illumination as one Jablochkoff lamp, would be 1,540 litere per hour. The price paid by the city to the gas company is O. fr. 15 cent. per 1,000 liters; hence, the expense of 1,540 liters would be O. fr. 23.1 cent. per hour. A careful estimate of the aggregate expenses of *each* Jablochkoff lamp shows that it is O. fr. 73 cent. per hour, so that we have the cost of 11 gas lamps = one Jablochkoff lamp = O. fr. 23 cent. per hour; cost of one Jablochkoff lamp = 11 gas lamps = O. fr. 73 cent. per hour. Hence, the Jablochkoff light is nearly 3.2 times as expensive as the gas light. This estimate is based upon the expense incurred in producing the light for 62 Jablochkoff lamps per hour, which required 77 horse-power.

The Commission proposes to pay the Jablochkoff company (which it accepted) O. fr. 30 cent. per lamp per hour for 83 lamps for one year. The total number of burning hours per year is estimated at 183,621 for the 83 lamps. Hence, the cost per year = 55,086 francs; cost of gas per year = 21,041 francs, for illuminating the *same places*. Hence, the *excess* of expense to city, in using electric light in place of gas light, will be 34,090 francs per year. But this credit is asked for in the *interest of science*.

People seem to have forgotten that only three years ago a competitive trial of gas and electricity was made in London in the Clock-Tower of the Houses of Parliament. Each of these lights were tried for several months, and after careful examination, *gas was successful*. The more recent experiments in London have *not* been in any degree more satisfactory.

"There is, however," says Mr. Preece, "a defect in gas light which remains to be eradicated, and that is the *color* of the light. The one great advantage which the electric light has over the gas is that the electric light, owing to its very high temperature, produces rays of every degree of refrangibility, and, therefore, as an illuminating power it is equal to that of the sun. But gas light, owing to the lowness of its temperature, is deficient in *blue rays*, and is, therefore, not so effective in discriminating colors as the electric light."

And it is proper to add, that a decided advance towards perfection in this direction in gas lighting has already been made in the "Albo-Carbon" process, by which the gas is enriched with the vapor of *napthaline*. The intensity of the light of a gas-burner has thus been improved from five to twenty times.

It has been proposed to avoid the *enormous loss* of the electric light produced by *sub-division*, by the *diffusion of a single light*. This plan has yet to be practically tested. Mr. Preece has shown "that when adding to the lamps by inserting more of them on the same circuit, or on a circuit so that the current is sub-divided, the light emitted by each lamp is *diminished* in the one case by the *square*, and in the other case by a *cube* of the number of lamps inserted."

There can be no question that the use of electricity for the production of light is a very *wasteful* as well as *costly* process; for the energy generated in the machine is *not* all consumed in the *lamp*, but is *distributed over the whole circuit*. It is *not*, therefore, as in the case of gas, *utilized exclusively in the place where it is wanted*. A very large fraction of the electric energy is wasted in maintaining the current required to produce the light.

Immense Glacial Remains.—Prof. F. V. Hayden says that on the east side of Wind River peak, Wyoming Territory, and on the east hase of Fremont peak, the remains of the huge glaciers which once covered the region have been discovered. On the west side of Wind River range, the moraines and glaciated rocks were found on an immense scale. He thinks on this side a glacier must have formerly existed having a length of 80 miles and a width of 12 miles with arms extended up the gorges of the stream to the very water divide.—*Eureka Sentinel.*

The nomination of Clarence King as Director of the Geological Survey has been confirmed by the United States Senate.

MECHANICAL PROGRESS.

Telegraphic Messages through Pneumatic Tubes.

Great are the economies of machinery. Two years ago the Western Union Telegraph Company came to the conclusion that the business of getting messages from the main office on Broadway to Wall street, New York, and back was costing the company and the public more than was necessary. In order to cheapen the expense of the large volume of business emanating in that part of the town, the company laid brass pipes, properly protected from the moisture, down Broadway and Wall and Broad streets to the Stock Exchange and the branch telegraph office there, and other pipes down to the Cotton Exchange, and to the branch offices near by there.

These were pneumatic tubes two and one-fourth inches in diameter. They were four in number—two of them "up" tubes, as they are called, worked by exhausting the air and making a vacuum, and two of them "down" tubes, worked by pressure. The messages were rolled up thereafter and placed in little leather boxes, open at one end and about six inches long, and shot back and forth between the main and branch offices, instead of being sent by messenger boys or telegraphed over the wires. The company is now exchanging from 3,000 to 4,000, and more, messages a day, through their pneumatic tubes, between the main office on Broadway and the branch offices at and near the Stock and Cotton exchanges.

It saves thereby the labor of at least 25 telegraph operators, and the public is saved much expense. The tubes are, two of them, 2,100 feet long (the Wall street tubes), and two are respectfully 3,000 and 3,500 feet long. They are worked by a steam engine which has a capacity of 76-horse power, but which is never called upon for half its resources. An engineer and four boys at the tubes are all the employees needed in place of the 25 skilled operators.

This system has worked so well in the business emanating in the commercial and financial quarters of the city, that it is to be extended to a new quarter, namely, Printing-House Square. And now pipes are being laid to connect the principal newspaper offices with the telegraph office. There will be only one pipe carried to Newspaper Row, it will be a down pipe, and will carry the loads of both special and Associated Press dispatches, which are sent daily and nightly from the Western Union building to the offices of the daily press. The tube will be operated, however, from time to time as an "up" pipe, after the proper signals, so as to bring back the empty boxes. This pipe will be two and a quarter inches in diameter, and 9,000 feet of it will be employed. Only the morning newspapers are taking advantage of the new system. The offices which have the tubes will have great gainers. They will get their dispatches 15 minutes earlier, at the least, an important matter late at night. The message will be delivered in 30 seconds. The Western Union and Associated Press will be able to save the expense of a great crowd of messenger boys. The pipes are being laid under the direction of Mr. Brown, Assistant Superintendent of the Western Union.—*N. Y. Corr. Philadelphia Press.*

How Millstones are Made of Glass.

The *Manufacturer and Builder* calls the attention of manufacturers who can cast heavy pieces of glass, and also of millers, to a recent German discovery, that the finest flour is produced by those millstones which have the most glassy texture and composition, and the consequent discovery that pieces of glass combined in the same way as the French burr and similarly grooved on their surfaces, will grind better than the burr millstones. The consequence of this discovery has been the invention of the glass millstones now made by Messrs. Thom, and used in Germany and Borkendorf with great satisfaction, as it is found they grind more easily, and do not heat the flour as much as is the case with the French burr stone. In grinding grist, they run perfectly cold.

In order to make such stones, blocks of glass of from 6 to 12 inches wide are cast in a shape similar to the French burrs, but more regular and uniform. They are connected with cement in the same way, and dressed and furrow-cut with picks and pointed hammers; but we believe that diamond-dressing machines might be profitably applied. It is said that these millstones, made of lumps of hard glass, do not wear away faster than the burr stones. Stones of four and a half feet in diameter, driven by six-horse power, ground 220 pounds of flour per hour, and did it while remaining cold. The grist is drier, looser, and the hull more thoroughly separated from the kernel than is the case with other stones.

If all this turns out to be correct, it is a valuable discovery, especially when we consider the expensiveness of good blocks of burr.

Experimenting.—The Pennsylvania railroad depot at Altoona was lighted by electric light recently. It produced a brilliant light, and gave general satisfaction. It was an experimental trial, but the company have no idea at present of adopting it.

Transmitting Power by Shafting.

In order to transmit the motion and power of a shaft, fitted in bearings, to one or more shafts occupying any desired and changeable position, Mr. Wilhelm Ritter, of Altona, Germany, proposes over one of the ends of a motive power shaft to place a box of a right-angle shaped bracket, and a conical wheel fastened to the outer end of this shaft. The other angle of the bracket is likewise formed as a box, the outer part of the boring being enlarged for the reception of a cylindrical prolongation of a similar bracket, and is furnished with a set screw to secure the second bracket, which can be turned within the enlarged boring of the first one in any desired position of a circle. A short axle passes through the box of the second bracket, the corresponding projection and the box of the first bracket, and each end of this short axle is furnished with a conical wheel fastened to it, and one of these wheels is in gear with the before-described wheel of the motive-power shaft, while the other conical wheel is in gear with a similar wheel fastened to the end of a shaft that revolves in the boring of the other box of the second right-angle bracket. By means of this gearing the shaft of the second bracket is put in motion, and the axis of this shaft can be turned into any position within the plane of a circle, after loosening the before-mentioned set screw, and turning the second bracket in the boring of the first one. After having brought the shaft of the second bracket in the desired direction, the position of the two brackets to each other is secured by means of the set screw. By means of two further pair of conical wheels, two more angle brackets of similar construction and connection, and another short axle, the transmission can be continued upon a third shaft, and the movableness of this third shaft will be greatly increased. The transmission of motion and power can in such manner be continued as far as necessary to other shafts, and the end of the last shaft may be constructed for the reception of a tool, or a pulley may be placed upon this shaft for driving a tool or implement. The conical wheels can be furnished with protecting covers.

A New Steam Wagon.

A new style of vehicle, designed to be propelled by steam, has recently made its appearance in London. The carriage closely resembles an ordinary dog-cart; the shafts are very short, and incline together, meeting two feet in front of the dashboard; between them there is a third wheel, working upon an upright shaft, which could be turned by a handle placed the same as that of a bycycle; this handle is worked by reins in the hands of the driver. The fuel used is benzine, and this burner used is described as being no larger than an ordinary bat. The steam is generated in a coil boiler of copper. The tubs of which the boiler is composed is stated to have been tested to a pressure of 2,000 pounds per square inch. This is, however, an unimportant matter, as the explosion of a coil boiler is never dangerous, and only results in putting out the fire and stopping the engine. The ordinary steam pressure is about 60 pounds. The vehicle is described as working very handily and being under very complete control. As only three or four persons are to be carried, the amount of power required is merely nominal. The speed, if we are not mistaken, was reported at something like 10 miles per hour. If there was any market for steam road wagons, or rather steam pleasure carriages, there would not be the least difficulty in producing them. The machinery needed is very light and can be stowed away beneath the seats or in the box, while the quantity of coal or benzine needed is very small. The speed of such machines is almost unlimited. Steam coaches on good roads have made as high as 35 or 40 miles in an hour, and from 12 to 18 were rates that were regularly maintained by some of the English steam passenger coaches before the railways drove them off from the common roads.

Brakes for Freight Trains.—The Master Car-Builders' Association, of New York, has recently discussed the subject of train brakes for freight cars. Most of the freight cars on American lines have hitherto been using the old windless brakes, worked by brakemen. In a train of 50 or 60 cars, often not more than three or four brakemen are employed, and hence a great deal of time is lost in applying the brakes to all the cars. For these and other reasons, freight trains hardly ever exceed a speed of 12 miles an hour. What the association seeks to accomplish is a uniform train brake, under the control of the engineer. Various brakes were mentioned, as the Stuart power brake, the Westinghouse brake, and other vacuum, steam and air brakes. The elevated railroads in New York use air brakes, and the Hudson River and New York and Harlem River railroads use automatic brakes on their passenger trains, but the companies have not yet been able to agree on any particular brake, partly because the appliance of the brake to the cars would entail considerable expense. Often cars of 20 or 30 different companies are run on the same train.—*Iron Age.*

A New Plan for Grain Elevators.—A recent number of the Toledo *Blade* gives an account of some experiments which have lately been made by Alfred Wilkin, of Toledo, for the construction of a machine for the movement of grain as if it were water; that is, for pumping it up in elevators by atmospheric pressure, or the exhaust-process which is applied to the celebrated Westinghouse atmospheric brakes. If this meets with the success which it promises, it will constitute an important improvement in handling grain.

Iron-Producing Countries of the World. The leading iron and steel-producing countries of the world, in the order of their importance, are enumerated as follows: Great Britain, United States, Germany, France, Belgium, Austro-Hungary, Russia and Sweden. These countries produce 98½% of the world's annual produce of iron and steel, and all were represented at the Paris exhibition except Germany.

SCIENTIFIC PROGRESS.

The Gyroscope—A New Law of Motion. (?)

The discovery of a new law of motion at this day might be considered somewhat apocryphal, and also that a clear solution of the mysteries of the gyroscope was within the grasp of the ordinary man of letters. Mr. James McCarroll, a resident of New York, appears to have worked out a theory respecting these two points, which certainly deserves the attention of the savants. Mr. McCarroll avers that all bodies moving in right lines change their distance from the center of gravity, and, consequently, their weight at every moment, and that when moving in curves, whether concentric with the circles of the earth or otherwise, the tangential force, antagonizing with that of gravity, serves to change their weight also. Hence he lays it down as a fourth law of motion that "a body is of uniform weight when at rest only."

In relation to the mysterious problem of the gyroscope, his demonstration is seemingly quite clear that a vertical wheel in motion does not press upon the same points of its bearings that it does when it is at rest, from the fact, as he alleges, that all the particles of matter in the periphery on one side of the wheel have a tendency to fly off at various angles in the line of the earth's gravity, and one of them directly in that line; while all the particles in the other half of the periphery have a tendency to fly off in a contrary direction, establishing an unequal distribution of force upon the axis and a minus and plus side of the wheel; as on the one side we have the earth's gravity, plus the tangential force of the wheel, and on the other its gravity minus that force. This, once admitted, the motion of the horizontal ring on which the vertical wheel revolves is apparent at once; for the ring, being free to obey any impulse given it in its own plane, simply retires before the plus side of the wheel and in a direction contrary to the revolution of the wheel itself. In explanation of the mysterious manner in which the whole weight of the gyroscope is sustained on one side of the upright pivot upon which the small projection from the horizontal ring rests freely, Mr. McCarroll says that when the vertical wheel is made to rotate so rapidly that the tangential force is in excess of that of gravitation on the whole mass, both ring and wheel will remain suspended, without any material support on one side of the upright, and be carried round the pivot upon which the projection from the ring rests, revolving more rapidly as the tangential force of the wheel decreases and is the more readily lent out of its plane, until, falling below the force exercised upon the whole mass by the gravity of the earth, both ring and wheel begin to gradually describe downward the arc of a circle vertical to a line tangent to the earth's surface, with the pivot for its center, and the axis of the wheel, together with the projection of the ring, for its radius, until, at last, the exhausted mass tumbles to the ground.

An Apparatus to Measure the Variations of Daylight.

It is greatly to be desired that a good and simple method be found of recording and measuring, with some accuracy, the variations of daylight throughout the day. This would render the weather record more complete, and it has an important special bearing on plant physiology. An attempt of the kind has lately been made by a German, Herr Kreusler, who has had made for him, by Liebertz, in Bonn, an apparatus with the following arrangement: It consists of a drum, fixed with its axis in the plane of the meridian, and adjustable so as to be at right angles to the sun's rays. This drum has its border divided into 24 hours—12 noon and 12 midnight being in the meridian plane. A strip of paper, sensitized with solution of bichromate of potassium, and having divisions which correspond to those on the drum, is placed round this. A second drum closely surrounds the first, and is turned by clock-work (from which it can be detached) once in 24 hours, in the direction of the sun's apparent course. The second drum has a slit for admitting light to the paper; its width is such that any point on the paper is exposed 20 seconds as the slit passes over. The whole apparatus is placed in the open air under a glass bell jar. Its arrangement gives little trouble; the paper strip has merely to be placed in its right position at night or under artificial shade (to avoid coloration), and the outer drum slid over and so attached to the rotating axis that the "insolation slit" is opposite the hour then present. The slit then begins to move round the inner drum correspondingly to the sun's course. The impressed slip, when removed in the evening, may be "fixed" by shortly dipping in water and drying between blotting paper, or it may not, being quickly read; it shows a mostly continuous succession of bands of various shades of black, or rather brown. For comparison, Herr Kreusler made a scale of 10 degrees of darkening, exposing strips of the paper a given time under different angles of incidents of light. Bands of the experimental strip that appear homogeneous are now measured with reference to breadth and intensity, and the sum of the products of those quantities is taken as a measure of the action of light rays falling on the instrument in a given time. The results are considered highly satisfactory.

Straw Dynamite.

By submitting straw to a boiling operation for 15 or 18 hours in an alkaline solution (salts of soda or of potash) at a temperature of 2° to 3° Baume, the straw is then easily disintegrated, and the fatty or other soluble matters which it contains are dissolved and carried off by the water, when the latter is withdrawn. The fibers are then triturated, and a perfect washing effected at the same time by means of either a cylinder stuff engine, similar to those used in paper mills, or by means of revolving millstones. During the trituration a current of water should constantly wash the fibers.

It is essential that this pulp does not retain any alkaline reaction, which is ensured by adding sulphuric acid or hydro-chloride acid in sufficient quantity that the washing water has a slightly acid reaction. The fibers thus triturated and prepared are, after having been perfectly dried, ready to undergo the reactions which render them explosive. To facilitate the manipulations, the pulp is treated by the paper machine, and should produce a sheet weighing about 300 grammes to the square meter. The thickness may be varied at will. The sheet thus formed is cut into fragments three or four millimeters square, immersed in nitro-sulphuric acid, and well washed. To transform the materials into nitro-cellulose more economically, the fragments may be immersed in a compound of nitrate of soda or of potash and concentrated sulphuric acid, the result being the same.

A nitro-cellulose of straw is, according to Mr. A. Lanfrey, of Chartres, France, thus obtained of a very energetic explosive property, and at the same time of great stability, qualities which the nitro-cellulose of cotton does not possess. The absolute stability of this nitro-cellulose, of such importance to explosive bodies, is thus explained. The fibers of the straw are formed of cellulose containing in the state of combination a considerable quantity of silica in the form of silicates. This silica acts in straw nitro-cellulose in the same way as in dynamite, fixing the nitro-glycerine, and giving a stability to this substance, which it does not possess when it is alone. For this reason he prefers oat straws, which contain more silica than the other straws, although they also give good products. The fragments of straw nitro-cellulose thus neutralized and retaining a slight alkaline reaction, are put, after having been drained, into a nitric solution containing dextrin, and if required powdered charcoal in a state of suspension. These solutions vary with the uses to which the explosive is intended to be put.

The Charms of Natural Science.—The Earl of Derby, in an address at the Edinburgh University, said: "Of the gains derivable from natural science I do not trust myself to speak; my personal knowledge is too limited, and the subject is too vast. But so much as this I can say—that those who have in them a real and deep love of scientific research, whatever their position in other respects, are so far at least among the happiest of mankind. * * No passion is so absorbing, no labor is so assuredly its own reward (well that it is so, for other rewards are few); and they have the satisfaction of knowing that, while satisfying one of the deepest wants of their own natures, they are at the same time promoting in the most effectual manner the interests of mankind. Scientific discovery has this advantage over almost every other form of successful human efforts, that its results are certain, that they are permanent, that whatever benefits grow out of them are world-wide. Not many of us can hope to extend the range of knowledge in however minute a degree; but to know and to apply the knowledge that has been gained by others, to have an intelligent appreciation of what is going on around us, is in itself one of the highest and most enduring of pleasures."

Nickel Plating without a Battery.—Prof. Slatba has invented and published a process for nickel-plating without a battery, which is said to give good results. The process is described as follows: To a dilute solution of chloride of zinc (5% to 10%) enough nickel sulphate is to be added to impart a decidedly green color to it, and the solution is then to be heated to boiling in a porcelain vessel. The clouding of the liquid from the separation of a basic zinc salt need not be heeded, as it will not interfere with the effectiveness of the bath. The articles to be nickel-coated—first carefully cleaned of oxide or grease—are to be suspended in the solution for from 30 to 60 minutes, the bath being kept at a boiling temperature. When the articles are observed to be uniformly coated, they may be removed, washed in water in which a little chalk is suspended, dried, and finally polished with chalk or other suitable material.

The Mining Share Market.

Though much of the same dull and hysterical feeling which has characterized the last few weeks still remains in the share market, there has been, during the present week, a firmer, steadier tendency of things—sufficient, at least, to form a contrast to the weak, insipid actions we have become accustomed to. The Comstock has remained stagnant, and, with few exceptions, met with limited sales. There was a brisk traffic in the new Bodie mines, presenting a remarkable contrast to the above. Indeed, these mines formed *the* feature of the week. The cause of this interest is the late ore discovery in the Mono-Bodie crosscut. In these, as in all the others, the advances were not so astonishingly large, but the amount of business transacted was inversely heavy. Real Del Monte was especially a favorite for some time. Early in the week there was a slight squabble for Justice, induced by the report that Schultz and his friends were seeking to gain control of the election to be held in May. Savage and Hale & Norcross also showed improvement; and, taking all in all, the quiet condition, the firmer tone, and the increased sales, there is settled feeling in the market that a steady forward movement is in contemplation.

News in Brief.

TRAVEL to Yosemite has set in.

GARABALDI has arrived at Rome.

AN earthquake lately shook up Cadiz.

THE rinderpest is prevalent in Bohemia.

VIGILANTS are active at Davis City, Ia.

PAPER napkins are increasing in demand.

ORANGES are cheaper than apples in Astoria.

IN March, the public debt increased $892,724.

THE Army Appropriation bill has passed the House.

NUMBER of silver dollars coined to date, 21,661,274.

THE Albanians will forcibly resist annexation to Greece.

THE Skagit (W. T.) gold mines are attracting attention.

THERE are 170 convicts in the Oregon penitentiary.

THE Mormon Conference met at Salt Lake, Sunday.

THE Workingmen's Free Library has 865 volumes.

CHINESE labor is becoming a drug in Los Angeles.

STONY POINT boasts of a healthy four-legged chicken.

THE paraffine beds of San Pete, Utah, are being opened.

ANOTHER British victory is reported from Lahore, India.

THE labor market promises to be unusually large this season.

HAY harvest will soon commence in Santa Cruz county.

THERE are 195,897 persons buried in Greenwood cemetery.

THIRTY-FOUR marriage licenses were issued in the city last week.

MACKEREL are being caught in large quantities near Monterey.

WHITE laborers have been substituted for Chinese on the Oroville railroad.

IN the Oliver-Cameron case the jury rendered a verdict for the defendant.

THE estimated cost of the Mexican International building is $800,000.

THE Egyptians have again defeated the Arabs, killing over 2,000 men.

THE telegraph wires were down between Ogden and Cheyenne on Sunday.

COYOTES are rendering the sheep business unprofitable in Colusa county.

THE people of American Fork, Utah, are destroying the grasshoppers with fire.

THE beach mines along the coast of Coos county, Oregon, are pay handsomely.

YOUNTVILLE, Napa county, experienced a slight shock of earthquake on Monday.

THE drilling of Bulgarians in Eastern Roumelia continues—70,000 men now being armed.

VANDERBILT is buying steel rails in England, paying an advance over American prices.

THE trial of Olive, the millionaire, and his two associates, who burned two men at the stake in Custer county, Neb., is now in progress.

AT a prison at Charkoff, Russia, 200 of the 500 prisoners have died within four months.

INDIANS are raiding the Yellowstone valley, killing the whites and capturing horses and cattle.

THE Russian police system is to be reconstructed as a concession to prevalent discontent.

ONE-QUARTER of the children in the public schools of Virginia City are down with the measles.

ANOTHER colonization scheme is organizing in New York, under Catholic guidance and capital.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

PLYMOUTH NOTES.—Cor. *Ledger*, April 5: The Hercules mine is making slow headway in sinking. One day last week a stream of water burst through the hanging wall, filling the shaft with water to the depth of 10 or 15 ft. It was soon taken out. Water, however, is flowing too fast to admit of rapid progress in sinking. Reports are afloat that the New London claim has been sold, and that the purchasers intend to start it up at once. There is a fair sized body of ore in sight. Considerable work was done on it years ago, and all the rock taken out paid well. Chas. Green & Co. took up the north extension of this claim last fall, but no work has been done on it yet. The contract for sinking in the Junior mine is finished.

OTHER ITEMS.—*Dispatch*, April 5: The joint shaft of the East Keystone and Niagara mines is now down about 60 ft, at which depth they have a two-ft ledge of good looking rock, showing some free gold. Mr. Parks, the superintendent of the Talisman mine, has let a contract to some Italians for sinking the shaft 100 ft deeper. The stockholders appear to have more confidence in the mine now than ever. Sutter is feeling "blue," owing to the probability that the Amador mill will be shut down for about six months during the coming summer, until the new shaft can be finished. Mr. Mello, of Butte City, has erected a little two-stamp quartz mill in the canyon between that place and the river, for the purpose of crushing rock taken from his claim near the same place.

INYO.

MONOCK.—*Independent*, Mar. 29: Distance made in tunnel, 1000 level, is 34 ft, the total length of tunnel being 1,308 ft. The ground for greater part of week has not broken very well, but is now very soft in face. The drift lately broke into manganese and clayey matter, which, taken with indications for the past two or three days, would lead us to believe that we have got through the limestone belt lying next to Confidence ore ground. Hope shortly to have some developments at face of tunnel. The shaft has been sunk 10 ft, and is now down 335 ft. The points where chlorides are at work—1000 level—are looking very promising. It has the appearance of opening out into an extensive body of ore.

THE EMIGRANT.—The prospects of the Emigrant are decidedly encouraging. Five stamps are pounding away continuously, and bullion shipments being made regularly. There is enough ore now uncovered to keep one battery running steadily for at least a year to come, by which time, if not before, a new shaft and other prospecting operations will be complete. The Emigrant is a paying property as it is, and owes much of its success to the really efficient management of Supt. Taylor. A concentrator is to be put to work at once upon the tailings at the old mill site; it is estimated that at least $20,000 can thus be got out of these tailings; the concentration will bring their value up to about $400 per ton, thereby effecting a material saving in hauling and subsequent pauwork.

MONO.

THE STANDARD.—*Mono-Alpine Chronicle*, April 5: The event of the past week is the re-discovery of the Burgess ledge, which twisted out of the drift north. It had pitched west. It seemed to run out entirely, but in a distance of 30 ft, came in more heavily freighted with gold than ever, but dipping to the east. There is no change in the Bruce, Gildea, or the several other faces on ledges outside of the old main Standard lode. The new air compressor has been fairly tested, and the work of driving the patent drills begun in earnest. One of these drills will be put to work in the south drifts and crosscuts of the Bulwer mine, connecting with the main shaft of the Standard ground. It has been finally decided to open a new level in the Standard, as well as continue sinking the shaft, which is now down 780 ft vertical. A station will be cut out at the 700 level and crosscutting, both east and west, begun at once. A 700 level in the Standard is going to give the "mother vein" theory a fairer test than all other works put together.

BULWER.—The crushing process at the Bodie mill ought to be satisfactory to the stockholders. Already $63,000 and upwards have been shipped, and there were over 700 pounds of amalgam awaiting the retort yesterday, and valued at $22,000 more, and not half the ore-pile has been put through yet. The result of that crushing of 1,000 tons promises to be nearly a quarter of a million dollars. The shutting off of ore extraction at the Bodie mine is not as much felt as expected.

BELVIDERE.—The upraise on the Great Western ledge, on the new development, continues in ore of same character. The excavation above the drift is about 10 ft in length and 12 ft in hight.

NOONDAY.—The drifts either way from the shaft are about 45 ft in length; stoping is still going on; ore holds out in size and quality. As soon as the Bechtel shipment is crushed, the Syndicate mill will commence on Noonday ore.

BLACKHAWK.—The west crosscut, 320 level, is in over 40 ft, and is being rapidly extended. Ore body in Warren lode, 220 level, is improving on south drift and holding its own north.

BOORER.—*Standard*, April 5: A few days ago Superintendent Ellsworth, of the Booker, in running a drift north from his shaft on his ledge, drifted directly into the Spaulding shaft, which is being sunk on an incline on its ledge, followed from the surface. The Spaulding people claim that the country is all interlaced with stratums of quartz, and that Mr. Ellsworth has followed one of these stratums off his main vein, and connected with their ledge. Accordingly, Mr. Harry A. Gould, foreman of the Spaulding, hulkheaded the drift and shut the Booker people out. Mr. Ellsworth took the offensive. His men broke down the hulkhead and practically took possession of the Spaulding mine by force. Mr. Gould says that the Booker people were armed. They threw a track across the shaft, and, it is said, are continuing the work of drifting north of the Spaulding incline. The latter mine has been shut down.

NEVADA.

KENTON.—*Transcript*, April 6: This mine is showing considerable improvement. Have seen considerable free gold in the ore the past two days. Will push the new winze ahead as fast as possible and open from the lower tunnel. The mill is running steadily day and night.

GOOSEN HILL.—Mr. John Black is opening up the Ooshen Hill gravel lead, three-quarters of a mile west of Rough & Ready. He has been at work there about three months, with four or five men, has put in over 3,000 ft of pipe, and will have sufficient water to run until the middle or latter part of June. The ground was prospected some years ago, and favorable indications were found.

NORTH BLOOMFIELD NOTES.—The Malakoff mining company have a full force—some 60 or 70 white men, and about 40 Chinese—at work, and the developments are as satisfactory as usual. Brockmyer & Haner, whose claim is just opposite the Malakoff Co.'s office, on Virgin Valley ravine, are working five or six hands, and meeting with good success. They rely entirely upon free water, and will doubtless have sufficient this season to make a run of from three to four months.

CONDENSED NEWS.—At Moore's Flat the Blue Banks claim is about ready to begin washing. The Boston is running full blast, working 30 men and paying $3 per day—the attempt to cut down the wages having been abandoned. The Chinese claims are also running full force. The Little York mining company is reported as having shut down, in consequence of the injunction granted the farmers by Judge Keyser. The Thomas mine, formerly the New England, is turning out considerable good ore which is said to be paying handsomely. The mine known as the Black Lead, near the Rocky Bar, is looking splendid. A small crushing last week turned out a little over $75 per ton. Assays of the Wyoming ore run as high as $700 per ton; free gold, $300; silver, $17; sulphurets, $389. The general average of the great bulk of ore is $17 per ton free gold, and from $98 to $108 concentrated sulphurets. The Badger Flat claim, in Pleasant valley, has been washing since last October. The owners expect to commence cleaning up this week. The machinery being put up on the Iron Clad mine, near Rough & Ready, is from the Montana mine, at Colfax. About 60 tons of ore per week is extracted from the Deadwood mine by the lessees. There are some 350 tons of fine looking ore on the dump. The mill is running night and day.

SAN BERNARDINO.

IVANPAH ITEMS.—Cor. *Index*, April 4: In the well known Alley mine the laws of geology are set at defiance; there is no regular stratification, and a mining man educated in Europe would say on examination, that there was no mine or the semblance of a mine there. Still the mine is yielding as rich ore as any in the State. It occurs in pockets or kidneys, and is found in such quantities as are fully satisfactory to the owners. The Alley mine is located on the west side of the mountain range immediately adjoining the well-known Alaska hill, on which the Lizzie Bullock, Beatrice, Monitor and other well-known mines are located. The Lizzie Bullock mine is owned and worked by Mr. J. A. Bidwell, who is also owner of the only mill now at work in the district. The well-known mine, the Stonewall, located on the hill to the east of the Alley, and is looking well. Mr. Harris has sunk an incline 50 ft deep from the third level. The incline shows good ore on both sides for the entire depth. He is running a tunnel to cut the bottom of the incline, and has about 20 ft to run before cutting the ledge; he will then commence stoping out the rich ore.

SHASTA.

WHISKY TOWN.—Cor. *Independent*, April 3: The mine of Strode & Co., (old Peckham mine) is in good condition. Since striking the ledge they have run about 200 ft on it. The ledge is about two ft wide at the end of the tunnel. The rock is very hard but it prospects well. A five-stamp mill is going up as rapidly as possible, and will be in working order about the last of next week. They have about 300 tons of quartz on hand. Work in the shaft of the extension, owned by Warfield, Blair & Co., had to be suspended on account of water caused by the recent rains. A tunnel is now being run to tap the shaft. They have an abundance of water to run the arastra. The rock is yielding about $30 per ton.

SIERRA.

PITTSBURG HILL.—Downieville *Messenger*, Mar. 22: The promising gravel mine, in which George and Johnny Sharp, of Green & Co.'s stage line are interested, located near Camptonville, Yuba county, is being rapidly developed with encouraging indications of a rich gravel bed. Four hundred ft of tunnel have been run, when the boys raised for 60 ft, tapping pay.

INDIAN HILL.—Fresse & Anderson, at this mining locality, are washing their dirt. Tom Jackson has several men in his hydraulic claim, with full head of water.

PHIPPS AND MINNESOTA.—Sam. Irean, from Minnesota, reports 18 inches of snow there, and miners waiting for spring to open. Alf. Bixby is constructing a ditch to bring water to his mine, to sluice of the croppings of his quartz ledge. Ike Boles is developing his lods. Sam. Irelan continues driving his tunnel ahead, which is now in 550 ft. Ledge is three ft thick.

TRINITY.

AT WORK.—*Journal*, April 5: The Dixion Bar company, having everything in complete working order, commenced washing gravel on Monday last, and the hydraulic works splendidly. The company's prospects are said to be encouraging and it is hoped their mine will yield labu ously. It is an enterprise in which considerable cash capital has been invested, and deserves unhounded success.

NEVADA.

WASHOE DISTRICT.

The non-receipt of our usual Washoe letter compels us to copy from the Gold Hill *News*, of the 8th inst., the following recent information in regard to the Comstock mines:

CON. VIRGINIA.—Have extracted 1,482 tons of ore during the past week. The repairs to shaft will be completed on Monday next, at which time they will start the joint west crosscut from the 850 station. This crosscut will be continued with all possible speed to the west wall, and will open up and thoroughly prospect the unexplored ground to the west of the shaft. The C & C shaft has been sunk 15 ft, and is now 105 ft below the 2150 level. The material in the bottom is somewhat softer. They will reach the 2350 level next Monday, but before opening the station will sink the shaft 40 ft below for a sump. The necessary surveys have been made for the south lateral drift to connect with the Sutro tunnel, and they only wait for a certified copy of the Sutro compromise before commencing work.

CALIFORNIA.—Have extracted 2,170 tons of ore during the past week. West crosscut No. 1 has been discontinued, the face showing strong indications of water. They will have to explore with a drill, and not run the risk of being driven out by water.

OPHIR.—The main incline has been sunk and timbered during the past week 12 ft; total depth on the stope, 16f ft below the 2200 level. The material passed through is still a vein formation, showing some streaks of quartz. The ore stopes show no material change since last report.

TROJAN.—Northeast drift, third station, has been advanced and timbered 39 ft; total distance passed upraise No. 4, 229 ft; material passed through, very loose quartz and porphyry; quartz giving low assays. West drift from northeast drift has been extended 25 ft through vein porphyry; total length, 40 ft. Second station, north drift, has been extended and timbered 55 ft, passing through a mixture of quartz and porphyry; quartz giving low assays.

EXCHEQUER.—Work was resumed last Wednesday in the north drift on the 2400 level. Since which time the drift has been advanced 18 ft, making total length of the same 316 ft. The material encountered during the past week has been porphyry and quartz of a very promising nature, and which continues to improve as they advance north.

CHOLLAR.—At the Chollar-Norcross-Savage shaft during the past week they have put up smokestacks for boilers to air compressor. Have made steam connection between compressor and boilers, and air connection between compressor and receiver. They have pumped daily about 105,000 gallons of water into the Sutro tunnel.

SILVER HILL.—During the past week the main incline has been sunk and timbered 16 ft. The east crosscut, 1100 level, has been run 36 ft, and drift south from small shaft 46 ft, leaving the distance to Silver Hill, north line, 16 ft. They intend to stop the work underground tomorrow to overhaul the incline engine and put on the new rope for the incline.

OVERMAN.—Since last report the winze has been sunk 12 ft, and north lateral drift extended 36 ft. The ground in the winze is working a little better; no other change. At the new shaft they struck a very strong flow of water on March 30th, and have sunk but five ft this week, but the water is decreasing and they hope to be able to make better progress.

JULIA.—The water in the incline has been reduced to close proximity to the 2400 level. Pumps have commenced drawing from the long south drift, also from east and west crosscuts. Winze sinking from 1800 level has attained a depth of 26 ft and is substantially timbered. Flow of water is slight and does not retard progress of sinking.

UNION CON.—On 1600 level the joint Mexican winze has been sunk and timbered 10 ft, making total depth on slope of 335 ft. The flow of water from east drift continues about two inches. A chamber excavated and the upraise started to connect with the joint Mexican winze being sunk from 1600 level; material passed through is a favorable looking vein porphyry showing some water in face. Main north drift extended 38 ft.

UTAH.—Our main incline has been sunk and timbered 24 ft the past week. The formation remains the same, also the flow of water. The new V-bob has been delivered and is now being put up on the surface to test before putting in place. We are now engaged in putting in a partition in the incline below the 1350 level to cause a current of air to flow to the bottom. All of our machinery is working well.

CON. IMPERIAL.—For the week ending to-day we have made the following progress: The south drift on our 2600 level has been advanced 29 ft; making total length of same to date, 157 ft. The face of this drift is in quartz, clay and porphyry; no water to impede the progress of our work. The north drift has been advanced 15 ft, making total length of same to date, 130 ft. Everything is running all right, and we shall in future be able to make more rapid headway in advancing work in the mine.

MEXICAN.—On our 2100 level the joint Ophir upraise is now up 94 ft. On our 2000 level the joint Union Con. west crosscut has been extended 10 ft; material passed through, favorable looking vein porphyry, showing some water; requires timbering. On our 1000 level the joint Union Con. winze has been sunk and timbered 19 ft; total depth, 365 ft on the slope below that level.

SAVAGE.—We are still delayed from shutting down the pump in the Hale & Norcross. Our retimbering in the incline is making good progress, water being below the 2000 level.

BELCHER.—The main incline has reached a depth of 37 ft below the 2500 level, having been sunk 24 ft during the past week. The crosscut on the 2360 level is in 54 ft. There is nothing new in any part of the mine.

ALPHA.—Nothing new at the mine. We have about completed the work of repairing and enlarging the station on 2135 level. Have not yet resumed work in joint winze. Everything is moving along as usual.

BELMONT DISTRICT.

BELMONT.—*Courier*, Mar. 20: The mine is looking well. Have advanced the south raise 20 ft during the past week in a good, strong vein of quartz, averaging three and one-half ft thick, with from 10 to 12 inches of same pay ore. In the 300 level drift running north the ground is very hard, and they have advanced same only seven ft. The stopes between 200 and 300 levels are yielding the usual amount of ore, and the pocket of ore found going down under the 200 level is getting larger every day. Number of tons extracted for the week, 10; average assay, $96.

HIGHBRIDGE.—Work in the mine has been carried forward with good progress, the ore extracted being unusually rich. The following work has been done in the prospecting drifts, showing no material change: Sixth level, 25 ft south and 32 ft north; seventh level, 23 ft north; total length of this level, 105 ft. The mill will resums reducing Highbridge ore by April 1st.

EUREKA DISTRICT.

THE PHŒNIX.—*Sentinel*, April 5: A marked improvement has taken place in the Phœnix mine within the last few days. The ledge has been cut in the drift from the 500 level, and looks most encouraging for a magnificent development. Sufficient work has not yet been done to accomplish anything beyond ascertaining the mere fact that there are several ft of good ore in sight. The ore body has steadily improved, day after day, since it was encountered. The average distance between the quartzite and shale in the Phœnix is about 75 ft. It is thus seen there is plenty of room for bonanzas of good size. The ore broken down thus far will lies in the drifts. The dump was not in readiness to receive it. This will be finished to-day, when the work of hoisting ore will be commenced immediately.

THE HAMBURG.—There is no special change to note in the stopes above the intermediate drift. The vein of ore is small, but of good quality. During the week the crosscut on the 450 level was advanced 14 ft, being a total of 23 ft, with the face in clay and iron. In the 000 level the west crosscut was advanced 16 ft, being a total of 218 ft, with the face in soft, broken limestone. The south drift from the west crosscut has been advanced 10 ft, being a total of 144 ft, showing a considerable amount of iron, with a number of small seams of good ore through it. In the 700 level the drift is now in 32 ft, through vein matter, showing bunches of iron.

TYBO CON.—The Tybo Con. is again in position to pay all claims against the company. The payment of local accounts was to have commenced yesterday. The mine and furnace have continued in operation right along since the financial troubles came up. It is thought the profits of the last month's run will realize some $40,000 or $50,000.

PARADISE DISTRICT.

GOOD HOPE NOTES.—*Silver State*, April 4: The shaft on the Snyder mine, owned by Waye & Co., has been sunk about 40 ft, and the ore encountered thus far is of a high grade. The Aurora mine is the deepest in the camp, and probably one of the best. The owners have sunk an incline shaft 140 ft, and have discovered some fine ruby and wire silver ore. The ledge is from two to four ft thick, well defined, and will average $100 per ton. It is owned by Winters & Co. The Silver Brick, owned by L. E. Atchison and others, is one of the most promising claims in the district. A north and south drift was started at the 65 level, and some ruby ore, assaying well, was found. On the Buckeye, a new claim, but little work has been done. The ledge was stripped on the surface for a distance of 60 ft, and the ore found was very rich. At a depth of 18 ft the ledge is three ft thick and well defined. This claim is owned by A. J. Dallas & Co. The You and I, the Atlantic Cable, and the Page & Kelley are good looking claims, upon each of which considerable work has been done, and from each of which ore of an excellent quality has been taken.

ARIZONA.

TOMBSTONE.—Cor. *Citizen*, Mar. 23: The Lucky Cuss is opening up in the tunnel wonderfully rich. The Old Guard has been worked on, and the Lucky Cuss ledge has been struck in this claim and the present shaft is all in rich ore, no walls being yet visible. Work has been suspended on the Merrimac for a few days. The reason is that the prospecting shaft has been sunk over 100 ft, and the owners are now satisfied that they have a mine and are going to sink a permanent working shaft and carry on work again in real earnest. Work was commenced on the Emerald yesterday. This claim is situated immediately south of the Grand Dipper. Work has been done on the Revenue mine, and some splendid ore set the mouth of the shaft. This claim is situated on the Lucky Cuss lead.

OLDER ITEMS.—*Silver Belt*, Mar. 23: Messrs. Allen & Skinner have been working the Despreciado mine and have obtained very good results. The ledge is 10 ft in width and assays from $30 to $150 per ton. Other work at various points on the claim shows good ore. Work is still progressing in the tunnel running for the Big Indian ledge, which is now in 80 ft. There is good ore in sight in the Oeueral Allen mine, and can be taken out at any time. The Fi Capitan mine is yielding ore worth from $300 to $400 per ton. A shipment is to be made to the Miami mill. Four men are at work. The Metamora shaft is over 100 ft deep, over six ft having been made last week. The quartz is still of a promising quality. Jack Eatoo, Whelan, Leuther & Co. have found good ore on the extention of the Barnes lode, at Pinto creek.

COLORADO.

SILVER CREEK.—*Miner*, April 5: Cavanaugh, Nash & Co. have leased 100 ft of ground near the breast of the O Connel tunnel. This is the lowest drift on the mine, and is 250 ft in length. A short distance back from the breast, where the lessees are commencing to stope, there is a vein of ore from two to ten inches in width. All the classes of the ore average nearly 400 ounces, and some of the first class run up to 900 ounces. The ore consists of galena carrying copper pyrites and gray copper, besides which there is some decomposed ore, though this stope is about 200 ft from the surface. The breast of the drift carries from two to three inches of ore, more or less decomposed, which assays from 208 to 926 ounces of silve

(Continued on page 244.)

A New Process for Treating Pyrites and Copper Sulphurets.

English technical journals seem to attach much importance to a process brought forward hy John Holloway, in a recent lecture before the Society of Arts. The idea, which has been broached repeatedly, though it has never undergone so complete a practical test, is borrowed from the Bessemer process. Air is blown into the sulphides previously melted in a cupola, to eliminate as much as possible the sulphur, thus concentrating the copper, by ons operation, in a rich regulus, instead of carrying it through numerous calcinations and fusions. The experiments made prove that the reactions in question take place, and on theoretical grounds no fault can be found with the process, but it is hard to see how it can be practically carried out on a large scale in an economical manner. The Bessemer converter, after trial by Mr. Holloway, has been abandoned by him as an unsuitable apparatus for this process. The best form of furnace for working the process cannot at present he decided upon, hut it is probable that eventually it will be a modification of the ordinary blast furnace, fitted with a tuyere hearth. The theory of smelting sulphides with a blast furnace is briefly as follows: The operation is started by putting the tuyere hearth in place and throwing hot coke at the top of the furnace; the blast is then turned on, and when the coke hecomes incandescent the working charge of sulphides and fluxes is introduced. As soon as a layer of molten sulphide is formed over the tuyeres the blast is increased, as also the burden of the furnace. The charge above the fusion zone becomes heated as it descends, losing much sulpher by volatilization as it melts, and also reducing the temperature of the gases as they pass upward. The sublimed oxides, eulphides and sulphur are collected in wide chamhers, with which the side flue is connected. On the hearth, where the air is forced in, the oxygen acts upon the sulphides of iron and zinc, and, as long as a constant supply of these substances is provided, nothing else is appreciably oxidized. The slag is withdrawn from a taphole near the top of the hearth, and the furnace is kept in action as long as the tuyere hearth lasts. The heat of the gases could be used for raising the temperature of the blast, or for producing the steam required to work the blowing engines. The produce of six tons of material would be tapped every half-hour, so that in seven days' continuous working 1000 tons of pyrites bearing sulphides would be treated. The sulphurous acid could be utilized in several ways, and Mr. Holloway acknowledges his indebtedness to Mr. A. H. Allen for the suggestion of a method by whicb large quantities of liquid, auhydrous, sulphurous acid could be converted into sulphuric acid, free from arsenic.

Leadville.

This infant city of the past year, with its closely huilt streets, its bustle of trade, its throng of teams that fill and hlock the way, and its surging masses of humanity that move in ceaseless currents from daylight until the midnight hour, is one of the marvels of the age. The site is favorahle—a smooth plateau, sloping gently to the west, rounding off into California gulch on the south, and rising to a slight ridge on the north. When the town began, the plat was covered with pine trees, hut nearly all have fallen, and each day diminishes the few that ought to be carefully preserved. Fortunately, thick forests surrounded it on all eides, and most of the timber is green, furnishing excellent huilding material at the lowest possihle cost. Building is going forward faster now than ever before, and the town spreads visibly day hy day. Along all the roads leading out north and east, strings of foundations, half built or completed cabins stretch continuously for a distance varying from half a mile to two miles. On the other sides they do not reach so far. There are hundreds, perhaps thousands, of these squatter claims, and it is nothing unusual to hear of their sale for $50, $100 or $200 each, when the improvement is nothing more than four logs, poles or slahs.

The altitude is about 10,400 feet ahove the sea, and the outlook is grand and magnificent. To the east, beyond the swelling green of the pine forests, are the shining peaks of the Park rango. Northward are lofty summits that close in the head of the Arkansas. Westward across the wide level valley are those stupendous masses, Massive mountain, Mount Elhert, La Plata mountain, and all the magnificent Sawatch range, here the mother mountains. Southward the view is down the valley of the river—a vanishing vista, shut in hy mountain walls.

Ths characteristics are thoss of any prosperous mining camp, but on a marvelous scale. There is an air of psrmanence not common to such, hut otherwise the history of its growth has hesn a hundred times repeated in California, Nevada and the Rocky Mountain States and Territories. Life is intensified. Everyhody who has anything to do is on the jump. The rasp of the saw aud tattoo of the hammer are heard from daylight to dark seven days in the week. Business occupies the same time and reaches far into the night as well. You must elbow and push your way thrcugh the crowds that fill the sidewalks aud wait for an opening in the teams and vehicles that throng the streets to cross from one side to another. Rents are fabulous. Real estate has advanced 1,000% in three or four months. Such is Leadville at a glance.—*Denver News.*

Lime for Adobe and Gypsum for Alkali.

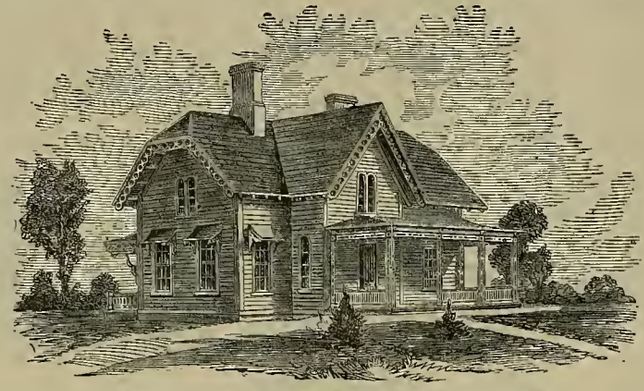
We have been interested in reading in the *American Journal of Science* a paper by Prof. E. W. Hilgard on the subject "Flocculation of Particles and its Physical and Technical Bearings." The paper is intended for the perusal of those who are interested in soil investigation from the scientific side, and is clad in technical language. We shall present in simpler form some of the conclusions arrived at by the writer and the reasons therefor.

The Professor speaks concerning two kinds of refractory soils; one strong clay or adobe, the other alkali; and the "flocculation of particles alluded to is the formation of fine particles which form these soils into floccules or small bunches. It will not he necessary for us to follow ths writer in his close and convincing argument as to the ways in which these floccules are formed, but it will suffice to show that upon their formation depends the tillability of the soils mentioned. On the one hand we have the fine single atoms of a clayey soil forced close together by the plow and "tamped" or "puddled," as it were, so that it is impossible to wholly break them down, and the only result of thorough plowing and harrowing is in reducing the size of the lumps but not destroying their cemented character. Ou the other hand we have the particles of the eoil first formed into floccules, so that the effect of tools is to sunder them and to give us a condition of fine tilth. The whole question of tillability in these soils seems then to restupon making the particlee into floccules, because if floccular they will not cement into lumps nor run together in a hard crust, as is their disposition if the particles are all free to act singly when they come under the plow or wben they are beaten by heavy rains.

This much premised .we may now quote a paragraph concerning the use of lime in rendering clay floccular in its structures. The Professor writes: "Let clay or clay soil be worked into a plastic paste with water and then dried: the result will be a mass of almost stony hardness. Add to the same paste about one-half of one per cent. of caustic lime, which substance (as shown hy Schlœsing and myself) possesses in an eminent degree the property of coagulating clay into floccules. The diminution of plasticity will he ohvious at once, even in a wet condition, and upon drying, the mass will fall into a pile of crumbs upon mere touch, or dropping it on the floor. This is a convincing illustration of the effect of liming upon clay soils in rendering them 'warmer' and more readily tilled. This agrees with the experience of farmers that the 'lightening' effect of a liming continues for years to he manifest and is never entirely lost." The deduction from tests made with the proper apparatus is that the action of lime is to cause the particles of the soil to assume the form of compound crumhs which fall apart when dry, because of the greater distance between them than between the particles when they are all free to run together when puddled hy heavy rains. It is because lime has this effect upon the particles of clay soil that its use in practice has been found very satisfactory.

Another instance of the beneficial effects of flocculation or crumhing, is seen in the effect of gypsum or land plaster upon alkali soils, which are rendered both infertile and untillable hy the preseuce of alkaline carbonates. Prof. Hilgard cites a case of alkali soil from near Stockton, of which some mention was made by him in an article for the PRESS last year. He made two analyses of adjacent soils, one being from a fertile ridge, another from an alkali spot lying ahout 18 inches lower than the ridge. The alkali soil had been plowed, cross-plowed, rolled and harrowed, until the harrow produced no farther effect; and the result was a seed-bed of soil clods ranging from the size of a pea to that of a billiard ball, but no tilth. At the same time portions of the ridge soil, cultivated in the same way, were reduced to an ashy condition of tilth. Examination showed that the two soils were almost alike in mechanical composition, but chemical analysis showed the alkaline carbonates in the intractable spots, and the presence of these prevented the floccular condition which we bave described. The application of gypsum, by decomposing these alkaline carbonates, enables the particles to flocculate or form crumbs, and thus become tillable. This was apparent at once in the experimental quantity of the soil used in the laboratory, but another season will be required to show the effect in ths field. Another effect of the plaster is in neutralizing the corrosive effect of the alkali upon plant growth, as has already been shown practically and on a considerable scale by the use of plaster on ths alkali soils in Los Angeles county.

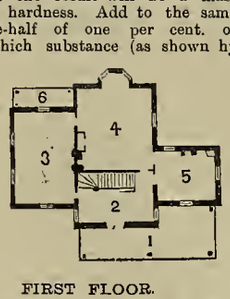
These are some of the points which Prof. Hilgard has placed before the scientific world concerning his investigation of our soil problems, and we doubt not we shall hear farther from him in the *Press* concerning the practical bearings of his studies.—*Pacific Rural Press.*



DESIGN FOR A MODEST FRAME COTTAGE.

A Cheap Frame Cottage.

We give on this page a design for a cheap frame cottage, which would make a modest pretty home for a small family. It is planned by Isaac H. Hobbs & Son, of Philadelphia, the intention being to secure good large rooms with no waste space and without expensive features in construction. In tbis, we think the architects have succeeded admirably. From the porcb one enters a hall 10x16 feet, with a window at each end, which would give as light and airy hall as one could wish. This is a desirable feature which is too often neglected in small houses. As will be seen by the dimensions which we shall give, the roome are all of generous size and well lighted. The projecting roof will help to cool the upper rooms, a fine feature in our warmer regions. Train some handsome climbing vines or roses over the porch and diversify the foreground more with handsome shrubs and flower heds, and one would have as cozy a home as could be longed for.



FIRST FLOOR.

SECOND FLOOR.

In the floor plans, No. 1, is the porch; No. 2, entrance hall, 10x16 feet; No. 3, living room, 14x20 feet; No. 4, dining room, 16x18 feet; No. 5, kitchen, 12x14 feet; No, 6, rear porch from which entrance can be had to the living room from the outside. It will be noticed that the house has no parlor. This is according to our "hobby." Put your best things in the living room and enjoy them.

TUNNELING THE DETROIT RIVER.—Mr. Vanderbilt is going actively at work to carry out the important transit improvement of tunneling the river at Detroit. Information has been received at that city to the effect that Mr. Vanderbilt has awarded the contract, and that work is to be begun the first week in April. The price is stated to he $1,500,000. The tunnel will extend from Stony island to Anderson, Ont., a distance of 3,700 feet, with douhle arches for a douhle track, 18 feet high and 15 feet wide.

THE ENGINEER.

Some Features of Ancient Engineering.

The following is an abstract of a paper lately read by Mr. George Burnham, Jr., before ths Engineers' Club of Philadelphia: Modern research has developed the fact that nearly all the materials (in a very wide sense of the word) of modern civilization originated in antiquity, the peculiar province of our time being to ring the changes of variety upon these elements and give them an immense diffusion.

The textile fahrics of wool, cotton, flax and silk were known to ths Egyptians of three or four thousand years ago, but the cotton-gin, the power-loom and thc steam engins have greatly increased their variety and put them into ths hands of everyone. The same thing is true of the engineering art, for, if we except iron framing, tbe ancients originated nearly all the typical forms we now employ. They wers acquainted with the constructive uses of wood, carried stone construction to a point that we have uever since reached, and probably never shall; their brickwork dates from the very earliest timies, and they constructed canals and aqueducts for irrigation, water supply and inland navigation, as well as elaborate drainage systems, long before their civilization culminated.

The Chaldean structures, dating from 2200 to 1500 B. C., were built of emall sun-dried bricks, laid in bitumen, and faced with kiln-dried bricks, stamped with the name of the king. These temples were built on elevated platforms of beaten clay, in some instances cased with massive walls of stone, the object being to raise them above the level of the plain for architectural effect and to avoid inundation. A brick burial vault at Mugheir exhibits a rudimentary arch. The vault is seven feet long, five feet high and three feet seven inches wide. The sides slope gently outward until the springing line is reached, wheu the successive courses are pushed toward each other until they meet at the top. Similar arches are found in early Greek work at Phigalia, Messene and other places.

The old notion that the round arch was of Roman, and the pointed arch of Gothic origin, has been dissipated by tbe spade of the archæologist. Both of these varieties are found in Assyrian work. They are usually of brick, and occur in underground conetruction, as drains and vaults. The brick arch existed in Egypt as early as 1540 B. C., and a stone arch has been found dating from 600 B. C.

The masonry of the past is, of course, identical with ours, since we have simply adopted the methods of the ancients. We find in Egypt and Western Asia smooth and rock-faced ashlar, rubble and irregular range work essentially like that of to-day. The Assyrian and Egyptian bas-reliefs indicate their method of moving heavy masses. Sledges were used, drawn by large bodies of men. Rollers were placed under the sledge, and the piece was carefully "guyed" by parties of men with appropriate ropes and props.

The Roman military roads crossed mountains and valleys without regard to the nature of the ground; tunnels, open cuts, embankments and bridges frequently occurring. Place cross ties and steel rails upon a Roman road aud suppose the grade not too steep, and the points of approach and divergence of modern and ancient engineering are at once apparent. Substantially the suhstructure was the same as that of a modern railroad, hut in place of the pedestrian or the ox team we have the locomotive, with its "fast express" or heavily laden freight train.

The Nicaragua Isthmus Canal.

A congress is now sitting in Paris, under the Presidency of M. de Lesseps, to decide between two rival French schemes for the construction of tbe canal to unite the Atlantic and Pacific oceans. One of tbese, the most plausible is that of M. Blanchet, a pupil of M. de Lesseps, who proposes to go farther north than the Isthmus of Darien, to avoid the numerous difficulties of that route, hy utilizing the Lake of Nicaragua. This plan bears some general resemblance to the American plan of Lull and Menocal, though it still differs from it both in principle aud in details. M. Blanchet proposes to start from the Pacific at Port Brito; then, after reaching the lake, shoot right across for the San Juan river, follow the river for nearly its entire course, and reach the Atlantic by a short cutting to San Juan del Norte. Port Brito and San Juan del Norte would, therefore, form the extremities of the canal. Lull and Menocal propose pretty much the same course, hut where M. Blanchet differs from them and from all other projectore who have suggested this route, is in his proposal to prolong the lake to the adjacent valleys on either side, and thus extend the area of lake communication between ocean and ocean—to do in fact what M. de Lesseps did at Suez with Timsah and Bitter lakes. The main point in all these Nicaraguan schemes is the existence of the lake. Here is a vast sheet of water stretching half way across the neck of tbe continent; here in fact is half your work done by nature. Now, M. Blanchet goes further, and says that with comparatively small labor you may virtually prolong this lake far down the San Juan valley on the Atlantic side and the Valley of the Rio Grande on the Pacific side. Then, as you approach the low-

lying lands at the nutlet (the lake being of a higher level than the adjacent ncean) ynu regnlate the flow hy a donble series nf locks nn the Atlantic side and a single series nn the Pacific side. M. Blanchet requires 14 locks for Nicaragua, while those called for by the Selfridge plan for Darien number 22; those nf the former, besides, lie together in groups, which makes them more easy nf management. The narrowest part of his canal is 164 feet wide, with a draft nf nearly 31 feet, and for the greater part of its cnurse it is, properly speaking, no canal at all, but a broad lake. Its estimated cost is about $40,000,000, which, doubled, would still leave a sensible difference in outlay between that and all other schemes. Thero is another consideration. As most of the trade of the world is with the northern rather than the southern half of the American continent, there will he a considerable saving of time and distance by the use of the more northerly routo. Vessels, for instance, sailing from the Gulf of Mexico to Califoruia, or the reverse, would gain nver 700 miles hy crossing at Nicaragua instead of at the isthmus. In addition to this, they would get rid of the risk of the frequent calms nf the Gulf of Panama, the outlet of the isthmus nn onc side, where sailing ships are eometimes detained for months at a time. The salubrity of Nicaragua ie an immense advantage, as facilitating the importation nf labor and the general prosecution nf the work. The canal of Selfridge, by Darien, taking its tortuous curves into accnunt, would be 204 miles long; the line nf communication in the Blanchet plan is actually less—only 180 miles. The Suez canal, it may be etated for purposes of comparison, ie 99 milee long. Thc lowest draft of water at Suez is 26.4 feet; at Darien, Selfridge would give a minimum of 26.2 feet, a trifle less; at Nicaragua, Blanchet would give a minimum of 31.4 feet. The Suez canal was estimated to cost $40,000,000, and the actual bill camo to $96,000,000. The Darien canal is estimated at $120,000,000; the Nicaraguan at $38,000,000.

From the Bosphorus to the Euphrates.

The constrnction of a railroad from some point on the Bosphorus on tbe Ægean sea, direct to the navigable waters of the Euphratee, is now a matter of eerioue consideration with English capitalists. Thc road will pass near the northeastern corner of the Mediterranean sea, and it is proposed to have the road touch that sea at some conveuient port—say at Pogas or Alexandretta, eo that direct communication cau he had with the road from those waters. Thie latter becomes a epecial matter of necesseity, now that Cyprus occupies so important a strategical a position in that region. So important a matter is this considered, it is admitted that, if neccsary, even an artificial harbor must he constructed at the point where the railroad touches the sea. Upon the question of conetructing such a harbor at some point fronting Cyprus, and the advantages that would accrue to British trade from its construction, correspondents, dating from Constantinople, write to the Liverpool Chamber of Commerce: "Just in front of Cyprus ie the Gulf of Iskenderun, otherwise Alexandretta, in which Ayaso is situated. Iskenderun would he one of the beet localities for a harhor, being well sheltered."

The advantages of a harbor at some or other of these points would give a great impetus, it is conceived, to the trade of the country, and facilitate and extend Britieh commerce with Turkey. The products of Great Britain are more eought after by the generality of the population than are those of any other foreign country, while the productions of France, Anetria, and Germany are in demand hy tbe higher classes. Openings for new undertakings, and for the establiehment of lines of eteamers, would, it is alleged, he favored and encouraged by the construction of a harbor, to which the abundant produce of the country would flow, as the outlet for its transit to other ports for consumption, and the center for a large British export and import trade.

Rocking Piers for Viaducts.—A novel conetruction has been recently described in *Engineering* as having been employed in the Dyedale viaduct, on the railroad from Christiana and Fredrikshald, carrying a single rail over the Dyse brook. These rocking piere for viaducts are intended to protect the etructure from the effects of expansion and contraction, due to alterations of temperature. The piers which support the superstruoture are of wrought iron with lattice-work weh. In the longitudinal direction of the viaduct, which is some 603 feet in length, there is only a single column hetween each span, poeeessing no stahility in iteelf, and the upper end is allowed to move along with the superstructure when the latter expands and contracts. The lower end of each pier rests on a hinged ehoe, eo that hreaking strains are avoided, and the load is alwaye rendered central to the pier columns. The movement of iron work in a longitudinal direction ie traneferred to the one abutment on which are the necessary bed plates, provided with rollers; on the other the euperetructure is kept in place hy a fixed shoe. With thie arrangement, it is stated that no epecial expansion joint in the raile is necessary, as the sleepers and platforms are quite independent of the expaneion and contraction of the ironwork.

Useful Information.

New Substitutes for Gold and Silver—Aphthite and Sideraphthite.

Some very beautiful alloys, applicable as substitutes for gold and silver in the manufacture nf jewelry and similar purposes, have been produced by Messrs. Meiffren & Co., of Marsoilles. To make an alloy having the appearance and color of gold, they place in a crucible copper as pure as possihle, platinum, and tungstic acid in the proportions below etated, and when the metals are completely melted, they stir and granulate them by running them into water containing 500 grammee of slaked lime and 500 grammes of carbonate of potash for every cubic meter nf water. Thie mixture, dissolved in water, has tbe property of rendering tho alloy still purer. Thcy then collect tho granulated metal, dry it, and after having remelted in a crucible they add a certain quantity of fino gold in tho proportion bereinafter epecified. An alloy is thus produced, which, wheu run into ingots, presents the appearance of red gold of the standard 750.1000, and to which may be applied the name of "aphthite," or unalterable. They can change the color of tho alloy hy varying the proportions of the different metals. As flux they use boric acid, nitrate of soda, and chloride of eodium previously melted together in equal proportions. The proportion of flux to be employed is 25 grammes per kilogramme of the alloy. The proportions they employ, by preference, for producing an alloy nf rod gold color are: Copper, 800 grammes; platinum, 25; tungstic acid, 10; and gold, 170 grammes.

The alloy used in imitation of eilver consists of iron, 65 parts; uickel, 23 parts; tungsten, 4 parts; aluminum, 5 parts; and copper, 5 parts. The iron and tungsten are melted together, and then granulated, as in the case of the previous alloy, except that in tbis instance the water into which the mixture ie run contains one kilogrammo of elaked lime and one kilogramme of carbonate of potash per cubic meter. The nickel, copper and aluminum are also melted together and granulated by running into water containing the eame proportion of lime and potaeh. Care should be taken during the melting tn cover the metals contained in the two crucibles with a flux composed of one part of boric acid to one part of nitrate of potash or niter. In the crucihle containing the aluminum and copper they place a lump of sodium of ahout two grammee in weight when treating five kilogrammes of the three metals (nickel, copper and aluminum) together to prevent oxidation of the aluminum, and they also add charcoal to prevent oxidation of the copper. Before granulating the metal in each crucible it should be well stirred with a fire-clay stirrer.

The granulated metals are dried, as in the former case, then melted together in the same crucihle in the proportions ahove indicated, and well stirred, after which the alloy is run into ingots. The alloy thus ohtained, to which may given the name of "sideraphthite" (or unchangeable iron) presents the same white appearance as platinum or silver, and is not more expensive than German silver. These improved metallic alloys are capable of reeisting the action of sulphureted hydrogen, are unattacked hy vegetahle acids, and but slightly attacked by mineral acids; they are aleo perfectly ductilc and malleable.—*London Mining Journal.*

The Latest New Thing—Banana Flour.—The banana has rccently found a new use in Venezuela. It has the property of keeping the soil moiet round it, in a country where sometimes no raiu falls for months; so it has been employed to give freshness, as well as shade, to the coffee plant, whose cultivation has been greatly extended (Venezuela produced 38,000,000 kilogrammes of coffee in 1876). The Venezuelans can consume hut little of the banana fruit thus furnished, so that atteution is being given to increasing its value as an article of export. At the Paris exhibition were samplcs of banana flour (got by drying and pulverizing the fruit before maturity) and hrandy (from the ripe fruit). The flour has been analyzed by MM. Marcano and Muntz. It. containe 61.1% of etarch, and only 2.9% of azotized matter.

How to Bronze Plaster Statues. — In bronzing plaster statues the powder ie dusted over the etatue while it is yet eticky from a coating of turpentine varnish. The hest way is firet to give a few coats of alcoholic shellac varnish, and then the coating of turpentine varnish, as otherwise the latter is too quickly absorbed. Let it stand till half dry and sticky and then dust over any color of bronze-powder to euit the case.

Zinc plates expand and contract strongly under the influence of change in the temperature, and become quite hrittle in the cold. Zinc, therefore, must be allowed plenty of play room. It should he attached either with nails of zinc or of strongly galvanized iron, as iron nails will rapidly rust out.

Gilt Lettering on Leather.—The leather is covered with white of egg where the lettering is to he done. A leaf of gold is laid on, and the letter punches heated over gas are pioked up and pressed gently on the leather in order. The remainder of the gold leaf is then brushed off hy a camel hair pencil.

Lead Alloys.

Ninety-four parts lead and six parts antimony form an alloy that may be rolled into sheets, and is a little harder than puro lead. This alloy is much used for sheathing for ships.

Twenty-four parts lead and four parts antimony form an alloy that is used in place of Babbitt metal for filling small boxes and bearings.

Twenty parts lead and four parts antimony form an elloy that ie eofter than tho above, and is used for the same purpose. Either of these may he hardened by the addition of more antimony; hut caro must he taken not to use too much antimony, for it will cause the alloy to lose its fluidity, and it cannot be run into the boxes.

All alloys of lead and antimony are rendered more fluid by meltiug them under a covering of oil.

Five parts lead and five parts tin make a heautiful white alloy, used for organ pipes. The mottled or crystalline appearance, so much admired in the pipe, is caused by using an abundance of tin.

One hundred parts lead and two parts arsenic form an alloy from which drop shot is made.

Eighteen parts lead, four parts antimony and one part hismuth form an alloy that expaude on cooling. This alloy is much used for metallic patterns for snap moldiugs.

Spelter-Solder Alloys.

A good solder for copper and iron ie composed of three parts zinc and four parts copper.

A eofter eolder that ie ueed for ordinary brass work is composed of equal parts of zinc and copper.

A very hard but fusible eolder is composed of two parts zinc aud one part copper. This eolder is eo hard aud brittle that it can he easily crumbled in a mortar when cold.

The two first solders are first alloyed and cast iuto ingots. The ingots are allowed to cool in the mold, and then reheated nearly to redness upon a charcoal fire, aud are broken up on the anvil, or iu a mortar, iuto a finely granulated state, for use.

Preserving Cements. — Protection from moisture, even that of air, is very essential for the preservation of cements, as well ae of quicklime. On this account the harrels are generally lined with etout paper. With this precaution, aided hy keeping the barrele stored in a dry place, raised above the ground, the cement, although it may require more time to set, will not otherwiee very appreciably deteriorate for six months; hut after 14 or 16 months, Gilmore says it is unfit for use in important works. But in lumps kept dry, it will remain good for two or three years, and may be ground as required for use.—*Trautwine.*

Good Health.

Utilization of House Wastes.

The whole catalogue of malignant and dangerous disorders, says an ex hange, are caused by the drainage o barnyards and filthy outbuildings into the well, wh ch is often placed so low as to take even the surface drainage, to say nothing of the liquid filth which soaks through the soil and poisons the currents that supply the wells with water. In addition to this, the wash water of the kitchen is often thrown out near the back door, instead of being carried away by a wide and free dram. And then very few people und rstand how dangerous to health are the decaying vegetables and all sorts of impurities that accumulate in cellars under houses, unless they are kept very dry and clean, and carefully watched. The above is excellent, but the New York *Witness* thinks there is more to be said, and adds: "One of the greatest securities of a house is to surround it with grapevines and roses. Though the fruit of the vines is most delici us, and the flowers of the roses most fragrant, the roots of both are just about the foulest feeders known. They will appropriate with astonishing avidity every kind of filth in the soils that would prove noxious to human life, and cesspools especially should be carefully surrounded by them. An amateur gardener informed us the other day of the astonishing success he had in growing peaches and pears from apparently worn-out trees by just using soap-suds and other slops of the kitchen to water them. He had completely overcome the borers by cleaning out a portion of the soil around the trees and filling the cup thus made with boiling soap-suds. And he had banished other insects by washing the bark of the stem with the same."

The above paragraph is making a circuit of our exchanges, and will we trust he productive of much good, for it is true and the advice given is most practical, if hut a little time he given to the application of it. Thinking, perhaps, some of our readers may he interested in some little dooryard irrigation echemes which we are introducing arouud our home in Berkeley, with a view to realizing the henefits of the fertilizing matter contained in house wastes aud in placing the same where they shall he inert in deleterious influencee upon the health of the household, we will give an outline of our operations.

We use the dry-earth system, indoors by means of a Wakefield earth closet, and outdoors by means of an outhouse which has no vault but a tight compartment helow, the floor of which is level with the surface of the ground in the rear and is closed hy a door hanging hy hingee on ite upper edge. In this box dry earth and coal ashes are thrown regularly and the contents deodorized. This material with the emptyings from the indoor earth closet is applied as a fertilizer inthe flower hede.

This provieion restricte the discharges from the waste pipes of the house to the soapy water from the hath-room, waeh-tuhs and kitchen-sink. The pipes connect with an iron stonepipe which leads to a cesspool four feet square and eight feet deep, with planked sides, which is sunk two feet below the surfaco of tbe soil, about 30 feet from the rear of the house. As the lot slopes toward the front, the water from the house is delivered at an elevated point. In to the cesspool is inserted a wooden pump, costiug $5, which raises the water in large quantities to its nozzle which is about three feet above the surface of the ground. As the slope briugs nearly the whole lot within reach of water flowing uaturally from the pump, we have made a lot of light V-shaped troughs, by nailing together pieces of half-inch redwood, aud around the lot, following the lines of the hedges and flower heds, we have a series of stationary supports into which a line of the troughs can he placed in a few minutes' time, and a stream of soapsuds can he sent along them from tbe pump to the farthest corner of the lot. We then put an assistant at the pump and manning tbc hoe nurselves we direct the water to the plants or uear them, and ae portions are sufficiently soaked we take off a length of trough, and so on until we have followed the line backward to the pump. Then the troughs are put on the supports aloug another line and tbe pumping hegins again; and so on until the plants are all irrigated or the cesspool pumped dry. Tben we go over the linee quickly with the hack of a rake, push the dry soil over the flooded spots, and the water is all covered under where it will do most good.

We could of course dig channele along the eurface of tho soil and let the water flow down them from the pump, hut this would flood the whole premisce and expose a large surface drenched with dirty water to tho eun, which would not he conducive to health nr comfort. By meaus of the troughs the water is easily carried over walke aud bordere without spilling, and after the dry earth is pushed hack and the surface leveled there is ecarcely a trace of the irrigation, and the earth effectually aheorbs all the deleterious qualities of the waste water.

Of course we mention our eystem only as applicable to small gardens and where the owner can take a delight in a littlo outdoor work himself at an odd hour. It might be an expensive way to dispose of sewage if one had to hire all the work done, hut as we practice it, we are freed from the neighborhood of an offensive cesspool or drains, and we have all the potash and other matter which we buy in eoap and all the fertilizing matter gained by cleansing processes, carried directly to the roots of our plants where it is made to do good eervice. With the aid of an assistant at the pump we can etow away ahout 800 gallons of water in an hour and a half, so that the undertaking is not a very arduous one.

Keep Dwellings Dry.

Saye the Cincinnati *Artisan:* "A warm and dry atmosphere is not unwholesome, but when cloudy or rainy weather hringe a sultry air which dampens everything around us, the atmoephere may be loaded with the germe of dieease, and fire is needed to destroy them. The walls, the ceilings and the floore of apartmente should never be allowed to become damp. Sometimes, when the warmth of the air is oppressive, fire is more necessary to preserve health than it ie at another season to protect us from the cold of winter; aud the rooms of a dwelling should nover be left without the meane of warming and drying. Investigations have shown that many of the most fatal diseaces are caused by the germs of vegetable and auimal life, and that a humid atmosphere is most favorahle for their propagation. It is, therefore, uegleeting to avail ourselves of the great discoveries of the age, and failing to protect ourselves from the ecourges which so fearfully afflict families, when we ignore the dangere which surround us. Apartmeuts exposed to the full action of the sun may be less comfortable in hot weather than those from which the sun'e raye are excluded, hut they are more wholesome, and when contagious diseaeee prevail in closely-built cities, it is fonnd that the inmates of housee on that side of the street expoeed to the suu are less liable to be attacked, while tbe greatcst nuniher of sick are alwaye found where there is the least exposure to the rays of that great disinfector—the sun.

Coffee as an Invigorator.—A correspondent of the London *Lancet*, who owue a waterpower mill, says: "I am frequently compelled, during this seasou of the year to havo men working in water even in frosty weather. I find that the following allowauce gives great eatisfaction to the men, and we never have a case of cold or injury to them in any way: Kettle of coffee made with half eweet milk, half water, three or four eggs, whipped, poured into when off the hoil; hot toasted bread with plenty of butter, fineet quality. Serve up thie every two and a half hours. The expense is much leee than the usual allowance of whisky and the men work far hetter, and if care ie taken to have the coffee, milk (cream ie still better), bread and butter of the very finest quality the men are delighted with it. I am persuaded it would he worth while to try this allowance instead of grog. Furnishing extra grog gives the men a notion that it ie good for them and perpetuates the belief in stimulants among workmen." [This would perhaps he a good drink for puddlers, especially iu hot weather, when they are often without appetite and weak on account of drinking too much water.]
